GS1 variant as well. In the following, the explicit enumeration of the type specific results for any particular GS1 code is omitted for sake of readability. Instead, the relevant result names are to be inferred from the result names for the corresponding non-GS1 code type and or be explicitly queried by `query_data_code_2d_params` with parameter `'get_result_params'`.

Candidate groups

The following candidate group names are predefined and can be passed as `CandidateHandle` instead of a single handle:

- `'general'`: This value is used for results that refer to the last `find_data_code_2d` call in general but not to a specific candidate.
- `'all_candidates'`: All candidates (including the successfully decoded symbols) that were investigated during the last call of `find_data_code_2d`.
- `'all_results'`: All symbols that were successfully decoded during the last call of `find_data_code_2d`.
- `'all_undecoded'`: All candidates of the last call of `find_data_code_2d` that were detected as 2D data code symbols, but could not be decoded. For these candidates the error correction detected too many errors, or there was an failure while decoding the error-corrected data because of inconsistent data.
- `'all_aborted'`: All candidates of the last call of `find_data_code_2d` that could not be identified as valid 2D data code symbols and for which the processing was aborted.

Supported results

Currently, the access to the following results, which are returned in `ResultValues`, is supported:

General results that do not depend on specific candidates – `'general'`:

- All data code types:
 - `'min_search_level'`: Lowest pyramid level that is searched for symbols. A pyramid level of 0 corresponds to the original image.
 - `'max_search_level'`: Highest pyramid level that is searched for symbols. A pyramid level of 0 corresponds to the original image.
 - `'result_num'`: Number of successfully decoded symbols.
 - `'candidate_num'`: Number of all investigated candidates.
 - `'undecoded_num'`: Number of candidates that were identified as symbols but could not be read.
 - `'aborted_num'`: Number of candidates that could not be identified as valid 2D data code symbols.
 - `'aborted'`: returns whether `find_data_code_2d` was aborted. This might be caused by a timeout (see `'timeout'` in `set_data_code_2d_param`) or an explicit abort (see `'abort'` in `set_data_code_2d_param`).

Value	Description
0	<code>find_data_code_2d</code> completed
1	<code>find_data_code_2d</code> was aborted by a timeout
2	<code>find_data_code_2d</code> was aborted using <code>set_data_code_2d_param</code> with <code>'abort'</code>

- Data Matrix ECC 200, Aztec Code, QR Code, and Micro QR Code:
 - `'quality_isoiec29158_labels'` and `'quality_aimdpm_1_2006_labels'`: Labels of grades for all tuple elements returned when calling `get_data_code_2d_results` with `'quality_isoiec29158'` or `'quality_aimdpm_1_2006'`.
- Data Matrix ECC 200, Aztec Code, PDF417, QR Code, and Micro QR Code:
 - `'pass_num'`: Number of passes that were completed, see also `find_data_code_2d` (Functionality of the symbol search).
 - `'quality_isoiec15415_labels'`: Labels of grades for all tuple elements returned when calling `get_data_code_2d_results` with `'quality_isoiec15415'`. The labels are different depending on the type of the evaluated data code symbol.

- Data Matrix ECC 200:

`'quality_semi_t10_labels'`: Convenience value labels of the elements of the tuple returned when calling `get_data_code_2d_results` with `'quality_semi_t10_values'`.

Results associated with a specific candidate - one value results:

Results that contain exactly **one value** and hence can be applied to a **candidate group** or a **specific candidate**. Please consider that some of the following results will only be meaningful if the candidate could be successfully decoded (see `'status'`).

- All data code types:

`'handle'`: Handle to the candidate. This parameter is used to receive the handles of all candidates of the specified group.

`'status'`: Indicates whether the decoding was successful or why the processing was aborted.

`'search_level'`: Pyramid level on which the finder pattern was found.

`'process_level'`: Pyramid level on which the candidate was processed and decoded.

`'polarity'`: Polarity of the symbol. This is the assumption about the polarity that was used for searching the candidate.

`'mirrored'`: Indicates whether a successfully decoded symbol is mirrored or not. For ECC 200, PDF417, QR and Micro QR Codes `'no'` or `'yes'` is returned. For Aztec Codes `'false'` or `'true'` is returned. For candidates that could not be read, the parameter returns the mirroring specification of the model.

`'orientation'`: Indicates the orientation of a successfully decoded symbol. The orientation is an angle relative to the orientation described in the figure below. The angle is positive in counter clockwise direction and is given in degrees. It can be in the range of $[-180.0 .. 180.0]$ degrees.

(1)

(2)

(3)

(4)

(5)

Orientation at zero degree of a Aztec symbol (1), ECC200 symbol (2), QR code symbol (3), PDF417 symbol (4) and DotCode symbol (5). The respective finder patterns or characteristic points are highlighted.

`'symbol_rows'`, `'symbol_cols'`: Data Matrix ECC 200, QR Code, Micro QR Code, Aztec Code, and Dot-Code:

detected size of the symbol in modules: number of rows and columns including the finder pattern;

PDF417:

detected number of rows and data columns (each 17 modules wide) within the symbol (excluding the start/stop patterns and the row indicators).

`'module_height'`, `'module_width'`: Height and width of the modules in pixels.

`'decoded_string'`: Result string that is encoded in the symbol – this query is useful only for successfully decoded strings. It returns the same string as `find_data_code_2d`.

`'decoding_error'`: Decoding error – for successfully decoded symbols this is the number of errors that were detected and corrected by the error correction. The number of errors corresponds here to the number of code words that lead to errors when trying to read them. For PDF417 this number includes erasures, i.e. errors with known locations. If the error correction failed, a negative error code is returned.

- Data Matrix ECC 200, Aztec Code, PDF417 QR Code, and Micro QR Code:

'*pass*': Number of the pass in which the candidate was generated and processed, see also [find_data_code_2d](#) (Functionality of the symbol search).

'*small_modules_robustness*': Robustness of the decoding of data codes with very small module sizes. For '*low*' the data code was decoded with a method that has only a small robustness regarding very small module sizes. For '*high*' the data code was decoded with a method that has a high robustness in this regard.

'*contrast*': Estimation of the symbol's contrast. This value is based on the gradient of the edge between the finder pattern and the background.

- Data matrix ECC 200, Aztec Code, QR Code, Micro QR Code, and DotCode:

'*module_gap*': Assumption about the module gap that was used for searching the candidate.

- Data matrix ECC 200, Aztec Code, QR Code, PDF417, and DotCode:

'*symbology_ident*': The *Symbology Identifier* is used to indicate that the data code contains the FNC1 and/or ECI characters.

FNC1 (*Function 1 Character*) is used if the data formatting conforms to specific predefined industry standards.

The ECI protocol (*Extended Channel Interpretation*) is used to change the default interpretation of the encoded data. A 6-digit code number after the ECI character switches the interpretation of the following characters from the default to a specific code page like an international character set. In the output stream the ECI switch is coded as '*\nnnnnn*'. Therefore all backslashes ('**', ASCII code 92), that occur in the normal output stream have to be doubled.

The '*symbology_ident*' parameter returns only the actual identifier value m ($m \in [0, 6]$ (QR-Code), $m \in [0, 12]$ (Data Matrix ECC 200 and Aztec Code), $m \in [0, 2]$ (PDF417) bzw. $m \in [0, 5]$ (DotCode)) according to the specification of Data matrix, QR Codes, Aztec Code, PDF417, and DotCode but not the identifier prefixes '*]d*', '*]Q*', '*]z*', '*]L*', and '*]J*' for Data matrix, QR Codes, Aztec Codes, PDF417, and DotCode, respectively. If required, this *Symbology Identifier* composed of the prefix and the value m has to be preceded the decoded string (normally only if $m > 1$) manually (for Data Matrix ECC 200 and Aztec Codes, the values 10, 11, and 12 have to be converted to A, B, and C, respectively).

GS1 symbologies have the following identifiers: '*]d2*' for GS1 DataMatrix, '*]Q3*' for GS1 QR Code, '*]z1*' for GS1 Aztec Code, and '*]J1*' for GS1 DotCode. Therefore, the '*symbology_ident*' parameter returns the values 2, 3, and 1, respectively.

Symbols that contain ECI codes (and hence doubled backslashes) can be recognized by the following identifier values: Data Matrix ECC 200: 4, 5, 6, 10, 11 and 12, QR Code: 2, 4, and 6, PDF417: 1, Aztec Code: 3, 4, 5, 9, 10, and 11, DotCode: 3, 4, and 5.

- Data Matrix ECC 200 and DotCode:

'*reader_programming*': If the symbol contains a Reader Programming character that indicates that the symbol encodes a message used to program the reader system, this parameter returns '*yes*', otherwise this parameter returns '*no*'. The decoded message does not contain the Reader Programming character.

- Data Matrix ECC 200:

'*slant*': Slant of the L-shaped finder pattern in radians. This is the difference between the angle of the '*L*' and the right angle.

'*finder_pattern_tolerance*': This parameter informs about the algorithm that found the symbol. For '*low*' the symbol was found with the algorithm that has only a small tolerance with respect to a defect or partially occluded finder pattern. For '*high*' the symbol was found with the algorithm that has a high tolerance in this regard. Please note that when using both algorithms simultaneously it may happen that symbols with an undisturbed finder pattern are found from the algorithm of high tolerance.

'*contrast_tolerance*': This parameter informs about the algorithm that was used to correct local contrast variations in the symbol search. For '*high*' the symbol was found using an algorithm to correct strong local contrast variations. For '*low*' the symbol was found with the faster algorithm, which however is less robust with respect to local contrast variations.

'*module_grid*': For symbols that could be decoded, this parameter informs about the algorithm that was used for calculating the module grid: If a variable grid was used it returns '*variable*', and otherwise '*fixed*'. For symbols that could not be decoded, it returns the method that was used during the last decoding trial or, if the candidate was rejected before the decoding, the corresponding model setting.

- QR Codes:

'version': Version number that corresponds to the size of the symbol (version 1 = 21×21 , version 2 = 25×25 , ..., version 40 = 177×177).

'symbol_size': Detected size of the symbol in modules.

'model_type': Type of the QR Code Model. In HALCON the older, original specification for QR Codes Model 1 as well as the newer, enhanced form Model 2 are supported.

'error_correction_level': If a candidate is recognized as a QR Code, the first step is to read the format information encoded in the symbol. This includes the level of error correction (**'error_correction_level'** $\in$ [**'L'** (Low), **'M'** (Medium), **'Q'** (Quartile), **'H'** (High)]).

'mask_pattern_ref': Additionally, the format information encoded in the symbol include a code for the pattern that was used for masking the data modules ($0 \leq \text{'mask_pattern_ref'} \leq 7$).

- Micro QR Codes:

'version': Version number that corresponds to the size of the symbol (version M1 = 11×11 , version M2 = 13×13 , version M3 = 15×15 , version M4 = 17×17).

'symbol_size': Detected size of the symbol in modules.

'error_correction_level': If a candidate is recognized as a Micro QR Code, the first step is to read the format information encoded in the symbol. This includes the level of error correction (**'error_correction_level'** $\in$ [**'N'** (None), **'L'** (Low), **'M'** (Medium), **'Q'** (Quartile)]).

'mask_pattern_ref': Additionally, the format information encoded in the symbol include a code for the pattern that was used for masking the data modules ($0 \leq \text{'mask_pattern_ref'} \leq 7$).

- PDF417:

'module_aspect': Module aspect ratio; this corresponds to the ratio of **'module_height'** to **'module_width'**.

'error_correction_level': If a candidate is recognized as a PDF417 the first step is to read the format information encoded in the symbol. This includes the error correction level, which was used during encoding (**'error_correction_level'** $\in$ $[0, 8]$).

'macro_exist': Symbols that are part of a group of symbols are called “Macro PDF417” symbols. These symbols contain additional information within a control block. For macro symbols **'macro_exist'** returns the value 1 while for conventional symbols 0 is returned.

'macro_segment_index': Returns the index of the symbol in the group. For macro symbols this information is obligatory.

'macro_file_id': Returns the group identifier as a string. For macro symbols this information is obligatory.

'macro_segment_count': Returns the number of symbols that belong to the group. For macro symbols this information is optional.

'macro_time_stamp': Returns the time stamp on the source file expressed as the elapsed time in seconds since 1970:01:01:00:00:00 GMT as a string. For macro symbols this information is optional.

'macro_checksum': Returns the CRC checksum computed over the entire source file using the CCITT-16 polynomial. For macro symbols this information is optional.

'macro_last_symbol': Returns 1 if the symbol is the last one within the group of symbols. Otherwise 0 is returned. For macro symbols this information is optional.

'quality_isoiec15415_float_grades': returns a tuple with the same assessment of print quality like **'quality_isoiec15415'**. For a PDF417 some grades are assessed with the international standard ISO/IEC 15416:2016. In compliance with the standard the grades are returned with one decimal place.

- Aztec Codes:

'format': String that corresponds to the format of the decoded symbol: **'compact'**, **'full_range'**, or **'rune'**.

'symbol_size': Detected size of the symbol in modules.

'layer_num': The number of layers as encoded in the mode message of the symbol.

'codeword_num': The number of codewords as encoded in the mode message of the symbol.

Results associated with a specific candidate - tuple of values results:

Results that return a **tuple of values** and hence can be requested only separately and only for a **single candidate**. Please consider that some of the following results will not return a useful value if the investigation of the candidate was aborted.

- All data code types:

'bin_module_data': Binary symbol data that corresponds to the classification results of the individual modules – a value of 0 means that the module was classified as background and 100 indicates that the module belongs to the foreground. Values between 0 and 100 can be interpreted as foreground or background. The model persistence must be 1 for this result (see [set_data_code_2d_param](#)). For DotCodes the model persistence does not matter. It shall be noted that the order of *'bin_module_data'* does not necessarily match the order of the modules, which can be retrieved using *'module_1_rois'* and *'module_0_rois'* via [get_data_code_2d_objects](#). Instead, the order for successfully decoded symbols depends on the actual *'mirrored'* status of the result, or the *'mirrored'* setting specified via [set_data_code_2d_param](#) for failed candidates.

'raw_coded_data': Data obtained by mapping the binary data to data words according to the particular coding scheme of the symbol type. Single bits may still be erroneous, and the words that are used for the error correction are still included.

'corr_coded_data': Data obtained after applying the error correction: erroneous bits are corrected and all redundant words are removed, but the words are still encoded according to the coding scheme that is specific for the data code type.

'decoded_data': Tuple with the decoded data words (= characters of the decoded data string) as Latin-1 or ASCII code (see also [Tuple / String Operations](#)). Additionally, decoded words can be encoded as JIS8 or Shift JIS characters (QR Code and Micro QR Code only) or GB2312 characters (QR Code only). Note that for QR Code and Micro QR Code the Kanji characters are not returned as single (Shift JIS) code points by [get_data_code_2d_results](#), but split into individual bytes.

- All data code types except DotCode:

'quality_isoiec15415': Tuple with the assessment of print quality in compliance with the international standard ISO/IEC 15415:2011. The first element always contains the overall print quality of the symbol; the length of the tuple and the denotation of the remaining elements depend on the specific data code type. According to the standard, the grades are whole numbers from 0 to 4, where 0 is the lowest and 4 the highest grade. It is important to note that, even though the implementation is based on the parts of the standard which are applicable to software, the computation of the print quality grades depends on the preceding decoding algorithm. Thus, different data code readers (of different vendors) can potentially produce slightly different results in the print quality assessment. See [set_data_code_2d_param](#) for how to set the algorithm used to determine the module grid for *Data Matrix ECC 200* codes with *'quality_isoiec15415_decode_algorithm'*.

Using these values requires a thorough understanding of the underlying algorithms, and we recommend to read ISO/IEC 15415:2011 along with this documentation.

We recommend to use high quality images without artifacts like defocus, noise, overexposure, or inhomogeneous illumination. Such artifacts influence the result of the print quality grading. Further, to obtain robust grading results, an effective resolution of at least ten pixels per module in width and height is required (see ISO/IEC 15415:2011, Chapter 7.3.3). The quality grades are only computed when the symbol region including the quiet zone is fully in the image, otherwise -1 is returned for the quality grades. For the reference decoding algorithm, more cases lead to quality grades equal to -1. Please refer to *'quality_isoiec15415_decode_algorithm'* for more information.

For the 2D data codes *ECC 200*, *Aztec Code*, *QR Code*, and *Micro QR Code* the print quality is described in a tuple with twelve elements: (*overall quality*, *contrast*, *modulation*, *fixed pattern damage*, *decode*, *axial non-uniformity*, *grid non-uniformity*, *unused error correction*, *reflectance margin*, *print growth*, *contrast uniformity*, *aperture*). For *QR Code* and *Micro QR Code* also the *format information* and *version information* are returned as additional grading parameters.

The definition of the respective elements is as follows: The *overall quality* is the minimum of all individual grades. The *contrast* is the range between the minimal and the maximal pixel intensity in the data code domain, and a strong contrast results in a good grading. The *modulation* indicates how strong the amplitudes of the data code modules are. Big amplitudes make the assignment of the modules to black or white more certain, resulting in a high modulation grade. It is to note that the computation of the modulation grade is influenced by the specific level of error correction capacity, meaning that the modulation degrades less for codes with higher error correction capacity. The *contrast uniformity* is the minimum modulation value found in any module. This value is no grade, therefore, it can have real values. It does not affect the *overall quality*. According to ISO/IEC 15415:2011, the *print growth* is no grade and is therefore not used for calculating the *overall quality*. Instead, it can be used as an additional information to find out, if the graphical features comprising the symbol have not shrunk or

grown from their nominal size. This means that the *print growth* gives some indication to which extent the dark and light modules fill out their module boundaries. The calculation of the print growth does not follow the scheme as specified by ISO/IEC 15415:2011, but instead it considers the specifications as stated by the ISO/IEC standard of the 2D data code to be examined. This means that the computation of the *print growth* for *Aztec Codes* is implemented as described in ISO/IEC 24778:2008. For *ECC 200* the corresponding standard is ANSI/AIM International Specification Data Matrix and for *QR Codes* as well as for *Micro QR Codes* the implementation follows ISO/IEC 18004:2006. For all 2D data codes described above, the *print growth* is calculated in horizontal and vertical direction. The reported grade is the lower rated of the pair.

The *reflectance margin* also indicates (like the modulation) how strong the amplitudes of the data code modules are. The difference to *modulation* is that *reflectance margin* assessed the correct classification of the modules. The fixed pattern of both ECC 200, Aztec Code, QR Code, and Micro QR Code is of high importance for detecting and decoding the codes. Degradation or damage of the fixed pattern, or the respective quiet zones, is assessed with the *fixed pattern damage* quality, which is based on the modulation values.

The *decode* grade indicates if a code was successfully decoded. The *decode* quality is graded 4 when the code could be decoded according to the reference decode algorithm defined in the standard, and 0, otherwise. Note that HALCON's decode algorithm differs from the reference decode algorithm. Thus, in many cases HALCON can decode the symbol although the decode grade according to the standard is 0.

Originally, data codes have squared modules, i.e., the width and height of the modules are the same. Due to a potentially oblique view of the camera onto the data code or a defective fabrication of the data code itself, the width to height ratio can be distorted. This deterioration results in a degraded *axial non-uniformity*. If apart from an affine distortion the data code is subject to perspective or any other distortions too this degrades the *grid non-uniformity* quality. As data codes are redundant codes, errors in the modules or codewords can be corrected. The amount of error correcting capacities which is not already used by the present data code symbol is expressed in the *unused error correction* quality. In a way, this grade reflects the reliability of the decoding process. Note, that even codes with an unused error correction grading of 0, which could possibly mean a false decoding result, can be decoded by the `find_data_code_2d` operator in a reliable way, because the implemented decoding functionality is more sophisticated and robust compared to the reference decode algorithm proposed by the standard.

For *QR Codes* and *Micro QR Codes* the additional grading parameters *format information* and *version information* are graded in a similar way to *fixed pattern damage*. If no *version information* exists, 'N/A' is returned.

For the 2D stacked code *PDF417* the print quality is described in a tuple with eight elements: (overall quality, start/stop pattern, codeword yield, unused error correction, modulation, decodability, defects, aperture).

The definition of the respective elements is as follows: The *overall quality* is the minimum of all individual grades. As the PDF417 data code is a stacked code, which can be read by line scan devices as well, print quality assessment is mainly based on techniques for linear bar codes: a set of scan reflectance profiles is generated across the symbol followed by the evaluation of the respective print qualities within each scan, which are finally subsumed as overall print qualities. For more details, the user is referred to the standard for linear symbols ISO/IEC 15416:2016. In *start/stop pattern*, the start and stop patterns are assessed concerning the quality of the reflectance profile and the correctness of the bar and space sequence. The grade *codeword yield* counts and evaluates the relative number of correct decoded words acquired by the set of scan profiles. For the grade *unused error correction*, the relative number of false decoded words within the error correction blocks are counted. As for 2D data codes, the *modulation* grade indicates how strong the amplitudes, i.e., the extremal intensities, of the bars and spaces are. The grade *decodability* measures the deviation of the nominal length of bars and spaces with respect to their reference length. And finally, the grade *defects* refers to a measurement of how perfect the reflectance profiles of bars and spaces are.

The *aperture* is the size of the synthesized aperture in units of the module size of the symbol. This aperture is used to obtain the reference gray scale image during the grading procedure. It is defined in ISO/IEC 15415:2011, Chapter 7.3.3.

To be able to compute the quality values for QR Code, Micro QR Code, PDF417, and Aztec Code, it is necessary that the parameter '*persistence*' (see `set_data_code_2d_param`) is set to a value greater than or equal to 0. For Data Matrix ECC 200, quality grading can also be performed with a '*persistence*' value of -1.

'quality_isoiec15415_values': returns a tuple with the raw values for all '*directly measurable*' grades (re-

ported by 'quality_isoiec15415'). These are grades, whose definition in the ISO/IEC 15415:2011 standard is a 'direct derivative' of the reflectance (i.e., the gray values) or of geometrical properties of the symbol, or grades that are the result of a 'direct counting'.

The returned tuple has the same order of elements as the corresponding result with 'quality_isoiec15415'. For the grades, which are excluded from these lists, the operator reports 'N/A'. For the 2D data codes *ECC 200*, *Aztec Code*, *QR Code*, and *Micro QR Code* the excluded grades are *overall quality*, *modulation*, *fixed pattern damage*, *decode* and *reflectance margin*. For the 2D stacked code *PDF417* the excluded grades are *overall quality*, *start/stop pattern*, *modulation*, *decodability*, *defects*.

Although the grades *modulation* (for *ECC 200*, *QR Code*, and *Micro QR Code*) and *modulation*, *decodability*, *defects* (for *PDF417*) generally are grading the reflectance properties of the symbol, the standard procedures for their computation involve the symbology decoding routine and error correction mechanism. Therefore there is no 'direct' raw measurement underlying these grades. The grade *start/stop pattern* (for *PDF417*) is excluded because it is a complex grade, which does not correspond to a single raw measurement value.

All values except the *print growth* are normalized between 0.0 and 1.0. Hence, for example, a *contrast* value of 0.75 will correspond to a gray value of 191.25 (for BYTE images). For the *print growth*, values between approximately -0.9 and 0.9 are possible as an output. A negative value corresponds to a *print shrinkage* whereas a positive value reflects a *print growth*. The values can be interpreted as the percentage share that a dark module occupies too little (*print shrinkage*) or too much (*print growth*) of its nominal module size. A value of -0.50 indicates for example that a dark module is 50% smaller as the nominal module size. If the *print growth* could not be calculated, the value is set to 'N/A'.

To be able to compute the quality values for QR Code, Micro QR Code, PDF417, and Aztec Code, it is necessary that the parameter 'persistence' (see [set_data_code_2d_param](#)) is set to a value greater than or equal to 0. For Data Matrix ECC 200, quality grading can also be performed with a 'persistence' value of -1.

- Data Matrix ECC 200:

'quality_isoiec15415_additional_reflectance_check': Returns the result of the additional reflectance check described in ISO/IEC 15415:2011 7.7. If the check is successful or one of the grades for Modulation, Decode, or Fixed Pattern Damage is smaller than 1, 'passed' is returned. If the reflectance interval in the extended area is within the reflectance interval of the code area including the quiet zone, 'passed' is returned, as well. If the extended region required for this check is not completely contained within the image, 'fov_too_small' is returned. If the check fails, 'failed' is returned. In the exceptional case that the quality assessment fails and all grades are -1, 'unchecked' will be returned.

'quality_isoiec15415_intermediate': Tuple with intermediate results that are determined during the assessment of print quality for ECC 200 codes in compliance with the international standard ISO/IEC 15415:2011 and ISO/IEC 16022:2006. Using these values requires a thorough understanding of the underlying algorithms, and we strongly recommend to read ISO/IEC 15415:2011 and ISO/IEC 16022:2006 along with this documentation.

A description of the intermediate results is given below. The returned intermediate grades ('quality_isoiec15415_intermediate') and values ('quality_isoiec15415_intermediate_values') are the minimal grades and values for the code under inspection. The names of the available intermediate results can be queried with 'quality_isoiec15415_intermediate_labels'.

- 'Rmin' and 'Rmax': The minimum and maximum reflectance value in the sample area of the symbol (see Chapter 7.6, ISO/IEC 15415:2011). There are no corresponding grades for these values.
- 'L1' and 'L2': The grades of the vertical and horizontal portions of the outside L of the fixed pattern as defined in Chapter M.1.2, ISO/IEC 16022:2006. The corresponding number of damaged modules is returned as value.
- 'QZL1' and 'QZL2': The grades of the vertical and horizontal portions of the quiet zone adjacent to L1 and L2, respectively (see Chapter M.1.2, ISO/IEC 16022:2006). The corresponding number of damaged modules is returned as value.
- 'Transition Ratio': The grade for the transition ratio test described in Chapter M.1.3 b), ISO/IEC 16022:2006. The transition ratio TR is returned as value. It measures the ratio between the number of transitions on the clock track and the associated solid area.
- 'Clock track regularity': The grade for the clock track regularity test as described in Chapter M.1.3 e), ISO/IEC 16022:2006. If for any group of five adjacent modules more than two modules are considered as errors, this grade is 0, otherwise its 4. There is no corresponding value.
- 'Clock track damage': The grade for the clock track damage (see Chapter M.1.3 f), ISO/IEC 16022:2006). The corresponding number of damaged modules is returned as value.

- *'Solid fix pattern'*: The grade for the solid fixed pattern (see Chapter M.1.3 g), ISO/IEC 16022:2006). The corresponding number of damaged modules is returned as value.
- *'Clock track and adjacent solid pattern'*: The overall grade for the clock track and adjacent solid pattern (see Chapter M.1.3 k), ISO/IEC 16022:2006). There is no corresponding value.
- *'Average grade'*: The average grade for the for the fixed pattern. It is based on the grades for the L1, L2, QZL1, QZL2, and the overall grade for the clock track and adjacent solid pattern (see Chapter M.1.4, ISO/IEC 16022:2006). There is no corresponding value.

The grade for *fixed pattern damage* for the symbol is given by the minimum of the grades for *'L1'*, *'L2'*, *'QZL1'*, *'QZL2'*, *'Clock track and adjacent solid pattern'* and *'Average grade'* (see Chapter M1.4, ISO/IEC 16022:2006).

'quality_semi_t10_values': Tuple with the assessment of the print quality in compliance with the international standard SEMI T10-0701.

We recommend to use high quality images without artifacts like defocus, noise, overexposure, or inhomogeneous illumination. Such artifacts influence the result of the print quality grading. Further, to obtain robust grading results, an effective resolution of at least ten pixels per module in width and height is required. The quality grades are only computed when the symbol is fully in the image, otherwise -1 is returned for the quality grades.

The direct mark quality is described in a tuple with 21 elements: [P1 Row, P1 Column, P2 Row, P2 Column, P3 Row, P3 Column, P4 Row, P4 Column, Rows, Columns, Symbol Contrast, Symbol Contrast SNR, Horizontal Mark Growth, Vertical Mark Growth, Data Matrix Cell Width, Data Matrix Cell Height, Horizontal Mark Misplacement, Vertical Mark Misplacement, Cell Defects, Finder Pattern Defects, Unused Error Correction]. Note that the *Unused Error Correction* is returned for each Reed-Solomon block. Therefore, the actual length of the returned tuple depends on the number of Reed-Solomon blocks.

The definition of the respective elements is as follows: The first eight entries contain the coordinates of the four corners. The first corner is located at the vertical finder pattern. The remaining corners follow contour clockwise (for non mirrored codes). With *Rows* and *Columns* the numbers of rows and columns of the code are reported.

The value for *Symbol Contrast* reports the contrast between light and dark classified symbol pixels with respect to the full gray value range (255 for byte images) in percent. *Symbol Contrast SNR* is the corresponding signal-to-noise ratio. If the value is infinite, *'N/A'* is returned.

The values for *Horizontal Mark Growth* and *Vertical Mark Growth* represent the width and height, respectively, of marked modules with respect to the sum of the width and height, respectively, of a marked module and a space module in percent. A value of 50% is optimal. If some parts of the alternating pattern are hidden, *'N/A'* is returned.

The values for *Data Matrix Cell Width* and *Data Matrix Cell Height* report the average module width and height. They are computed from the four corner points and the number of rows and columns of the code.

The values for *Horizontal Mark Misplacement* and *Vertical Mark Misplacement* report the displacement of the alternating pattern marks' centers in horizontal and vertical direction, respectively. These values are given in percent with respect to *Data Matrix Cell Width* and *Data Matrix Cell Height*, respectively. If some parts of the alternating pattern are hidden, *'N/A'* is returned.

The value for *Cell Defects* reports the percentage of incorrectly classified symbol pixels.

The value for *Finder pattern Defects* reports the percentage of finder pattern pixels that would be classified incorrectly.

The value for *Unused Error Correction* reports the error correction capacities that are not already used by each Reed-Solomon block.

'quality_semi_t10_labels': Convenience value labels of the elements of the tuple returned when calling `get_data_code_2d_results` with *'quality_semi_t10_values'*. If the ECC 200 code has more than one Reed-Solomon block, the label tuple is extended by the corresponding values.

'quality_isoiec15415_reflectance_margin_module_grades': Tuple with the reflectance margin module grades that are determined during the assessment of print quality according to the ISO/IEC 15415:2011 standard Chapter 7.8.4.3. This includes the finder pattern modules and the 4 quiet zones adjacent to the symbol (2 horizontal and 2 vertical).

If the symbol size is *Rows* ·

Columns, the tuple size is $(Rows + 2) \cdot$

$(Columns + 2)$ as the 4 quiet zones are included. The tuple is sorted row by row, where the first row is the upper quiet zone and the last row is the bottom one (or QZL2 as described in ISO/IEC 16022:2006 Annex M.1.2, Figure M.1).

The computed grades for each module will be in the range 0 to 4. For unused data modules the module grade is not computed, in this case the corresponding tuple value will be -1.

'quality_isoiec15415_rows': Tuple with the image row coordinates of the points within the symbol modules for which the module grades are computed with the parameter **'quality_isoiec15415_reflectance_margin_module_grades'**.

The returned tuple has the same number and order of elements as the corresponding result with **'quality_isoiec15415_reflectance_margin_module_grades'**.

'quality_isoiec15415_cols': Tuple with the image column coordinates of the points within the symbol modules for which the module grades are computed with the parameter **'quality_isoiec15415_reflectance_margin_module_grades'**.

The returned tuple has the same number and order of elements as the corresponding result with **'quality_isoiec15415_reflectance_margin_module_grades'**.

'quality_isoiec29158_reflectance_margin_module_grades': Similar to **'quality_isoiec15415_reflectance_margin_module_grades'** but in compliance with the ISO/IEC TR 29158 (AIM DPM-1-2006) print quality standard.

'quality_aimdpm_1_2006_reflectance_margin_module_grades': See the entry for **'quality_isoiec29158_reflectance_margin_module_grades'**.

'quality_isoiec29158_reflectance_margin_module_float_grades': Similar to **'quality_isoiec29158_reflectance_margin_module_grades'** but in compliance with the ISO/IEC 29158:2020 print quality standard. The underlying grades are returned with one decimal place.

'quality_isoiec29158_rows' and 'quality_aimdpm_1_2006_rows': Similar to **'quality_isoiec15415_rows'** but related to **'quality_isoiec29158_reflectance_margin_module_grades'** and **'quality_aimdpm_1_2006_reflectance_margin_module_grades'**.

'quality_isoiec29158_cols' and 'quality_aimdpm_1_2006_cols': Similar to **'quality_isoiec15415_cols'** but related to **'quality_isoiec29158_reflectance_margin_module_grades'** and **'quality_aimdpm_1_2006_reflectance_margin_module_grades'**.

- Data Matrix ECC 200, Aztec Code, QR Code and Micro QR Code:

'quality_isoiec29158' and 'quality_aimdpm_1_2006': Tuple with the assessment of print quality in compliance with ISO/IEC TR 29158. This standard was previously established by the Automatic Identification Manufacturers as AIM DPM-1-2006. ISO/IEC TR 29158 is an extension to ISO/IEC 15415:2011 standard, which defines certain requirements for the gray-scale properties of the data code image and in doing so improves the reproducibility of the grading results among different vendors.

Using these values requires a thorough understanding of the underlying algorithms, and we recommend to read ISO/IEC TR 29158 (AIM DPM-1-2006) and ISO/IEC 15415:2011 along with this documentation.

It is very important to note that an ISO/IEC TR 29158 (AIM DPM-1-2006) standard conforming print quality assessment requires interactive image acquisition! No images of a data code symbol should be regarded if there is no information for the camera-lighting setup used to acquire these images. In most cases this implies that the user should set up and use her/his own camera-lighting configuration. Refer to ISO/IEC TR 29158 (AIM DPM-1-2006) for some prescribed camera-lighting configurations and general configuration principles that are relevant for the standard. Note also that, even though the implementation is strictly based on the standard, the computation of the print quality grades depends on the decoding algorithm used. Thus, the print quality inspection results are relevant only for the 2D data code reader implemented with HALCON.

Calling `get_data_code_2d_results` with argument **'quality_isoiec29158'** or **'quality_aimdpm_1_2006'** assumes that the image being processed fulfills the two criteria explained in detail below. The returned tuple represents the 13 print quality elements: [overall quality, cell contrast, cell modulation, fixed pattern damage, decode, axial non-uniformity, grid non-uniformity, unused error correction, mean light, reflectance margin, print growth, contrast uniformity, aperture]. The first eight as well as the last four grades have the same meaning as the ISO/IEC 15415:2011 grades with two exceptions: *contrast* and *modulation* are renamed to *cell contrast* and *cell modulation*, respectively, to reflect differences in the methods specified with both standards for estimating those values. The value of *mean light* is not a grade specified with ISO/IEC TR 29158 (AIM DPM-1-2006) standard. It is an estimation for the quality of the processed image computed as the mean gray-scale value of the centers of the light data code modules. It is a value between 0.0 and 1.0, corresponding to 0% to 100% of the maximum gray-scale value (255 for byte images). For *QR Code* and *Micro QR Code* also the *format information* and *version information* are returned as additional grading parameters.

The essence of the standard is a procedure for the adjustment of the camera system response (SR): *exposure time*, *gain* and/or another specific setting of the user's camera-lighting setup. The goal is to obtain an image of the inspected data code symbol with optimal gray-scale properties. In the image processing context, which is in the main focus of the standard, this is also the key to reproducibility of the grading results. An image has the required gray-scale properties when its '*mean light*' value is between 70% and 86% (0.70 and 0.86, respectively). Trying to achieve this condition for images of physically low-contrast data code symbols results usually in very high SR levels. Therefore, the standard defines additionally a calibration routine, which identifies for comparison purposes the normal (calibrated) system response settings (SRcal) by evaluating images of an object with well-known reflectance properties (such as NIST traceable calibrated conformance test card). Finally, the **two image acquisition criteria** for an image read: **first**, the image must have a *mean light* value between 70% and 86% (0.70 and 0.86, respectively); **second**, it has to be obtained with system response (SR) settings fulfilling: $SR/SRcal \leq 16$. If no image of the data code symbol can be obtained to fulfill both criteria, the symbol must be graded with 0.

As neither the adjustment of the system response nor the verification of the SR criterion can be carried out from within a HALCON operator, the assessment of the AIM DPM-1-2006 quality grades should be performed in an appropriate program setup. The user is referred to two example programs provided with her/his installation of HALCON (calibration_aimdpm_1_2006.hdev and print_quality_aimdpm_1_2006.hdev in the directory HALCONEXAMPLES/hdevelop/Identification/Data-Code), which demonstrate the calibration and the grade evaluation routines, respectively. Both image criteria, as well as further details regarding the general camera setup and image acquisition are also explained and demonstrated there. Everyone who intends to use the AIM DPM-1-2006 grading standard can use the programs as a starting point and adapt them for her/his own camera-lighting setup.

The *aperture* is the size of the synthesized aperture in units of the module size of the symbol. This aperture is used to obtain the reference gray scale image during the grading procedure and selected by the procedure described in ISO/IEC TR 29158 (AIM DPM-1-2006), Chapter 7.3.

To be able to compute the quality values for QR Code, Micro QR Code, PDF417, and Aztec Code, it is necessary that the parameter '*persistence*' (see [set_data_code_2d_param](#)) is set to a value greater than or equal to 0. For Data Matrix ECC 200, quality grading can also be performed with a '*persistence*' value of -1.

'quality_isoiec29158_values' and 'quality_aimdpm_1_2006_values': Similar to '*quality_isoiec15415_values*', the raw values for all '*directly measurable*' grades are reported but in compliance with the ISO/IEC TR 29158 (AIM DPM-1-2006) print quality standard. The list of the reported and the excluded raw measurement values is the same as with '*quality_isoiec15415_values*'. The auxiliary ISO/IEC TR 29158 (AIM DPM-1-2006) grade *mean light* is reported in the same format (between 0.0 and 1.0) both by '*quality_isoiec29158*' and '*quality_isoiec29158_values*' ('*quality_aimdpm_1_2006*' and '*quality_aimdpm_1_2006_values*').

To be able to compute the quality values for QR Code, Micro QR Code, PDF417, and Aztec Code, it is necessary that the parameter '*persistence*' (see [set_data_code_2d_param](#)) is set to a value greater than or equal to 0. For Data Matrix ECC 200, quality grading can also be performed with a '*persistence*' value of -1.

'quality_isoiec29158_float_grades' Similar to '*quality_isoiec29158*', but with continuous grading following ISO/IEC 29158:2020. The underlying grades are returned with one decimal place.

To be able to compute the quality values for QR Code, Micro QR Code, and Aztec Code, it is necessary that the parameter '*persistence*' (see [set_data_code_2d_param](#)) is set to a value greater than or equal to 0. For Data Matrix ECC 200, quality grading can also be performed with a '*persistence*' value of -1.

- Data Matrix ECC 200:

'quality_isoiec29158_intermediate' and 'quality_aimdpm_1_2006_intermediate': Tuple with intermediate results that are determined during the assessment of print quality of ECC 200 codes in compliance with the international standards ISO/IEC TR 29158 (or AIM DPM-1-2006), ISO/IEC 15415:2011 and ISO/IEC 16022:2006. Using these values requires a thorough understanding of the underlying algorithms, and we strongly recommend to read ISO/IEC TR 29158 (AIM DPM-1-2006), ISO/IEC 15415:2011 and ISO/IEC 16022:2006 along with this documentation.

A description of the intermediate results is given below. The returned intermediate grades ('*quality_isoiec29158_intermediate*' or '*quality_aimdpm_1_2006_intermediate*') and values ('*quality_isoiec29158_intermediate_values*' or '*quality_aimdpm_1_2006_intermediate_values*') are the minimal grades and values for the code under inspection. The names of the available

intermediate results can be queried with *'quality_isoiec29158_intermediate_labels'* or *'quality_aimdpm_1_2006_intermediate_labels'*.

- *'T2'*: The threshold created using the histogram of the reference gray-scale image pixel values at each intersection point of the grid using the method defined in Annex A, ISO/IEC TR 29158 (AIM DPM-1-2006).
- *'MD'*: The value for MeanDark corresponding to T2, which is determined using the method defined in Annex A, ISO/IEC TR 29158 (AIM DPM-1-2006).
- *'MLtarget'*: The value for MeanLight corresponding to T2, which is determined using the method defined in Annex A, ISO/IEC TR 29158 (AIM DPM-1-2006).
- *'L1'* and *'L2'*: The grades of the vertical and horizontal portions of the outside L of the fixed pattern as defined in Chapter M.1.2, ISO/IEC 16022:2006. The corresponding number of damaged modules is returned as value.
- *'QZL1'* and *'QZL2'*: The grades of the vertical and horizontal portions of the quiet zone adjacent to L1 and L2, respectively (see Chapter M.1.2, ISO/IEC 16022:2006). The corresponding number of damaged modules is returned as value.
- *'Transition Ratio'*: The grade for the transition ratio test described in Chapter M.1.3 b), ISO/IEC 16022:2006. The transition ratio TR is returned as value. It measures the ratio between the number of transitions on the clock track and the associated solid area.
- *'Clock track regularity'*: The grade for the clock track regularity test as described in Chapter M.1.3 e), ISO/IEC 16022:2006. If for any group of five adjacent modules more than two modules are considered as errors, this grade is 0, otherwise its 4. There is no corresponding value.
- *'Clock track damage'*: The grade for the clock track damage (see Chapter M.1.3 f), ISO/IEC 16022:2006). The corresponding number of damaged modules is returned as value.
- *'Solid fix pattern'*: The grade for the solid fixed pattern (see Chapter M.1.3 g), ISO/IEC 16022:2006). The corresponding number of damaged modules is returned as value.
- *'Clock track and adjacent solid pattern'*: The overall grade for the clock track and adjacent solid pattern (see Chapter M.1.3 k), ISO/IEC 16022:2006). There is no corresponding value.
- *'Distributed damage grade'*: The average grade for the for the fixed pattern. It is based on the grades for the L1, L2, QZL1, QZL2, and the overall grade for the clock track and adjacent solid pattern (see Chapter M.1.4, ISO/IEC 16022:2006, and Chapter 9.4, ISO/IEC TR 29158 (AIM DPM-1-2006)). There is no corresponding value.

The grade for *fixed pattern damage* for the symbol is given by the minimum of the grades for *'L1'*, *'L2'*, *'QZL1'*, *'QZL2'*, *'Clock track and adjacent solid pattern'* and *'Distributed damage grade'* (see Chapter M1.4, ISO/IEC 16022:2006).

- Data Matrix ECC 200, QR Code, Aztec Code, and DotCode:

'structured_append': If the symbol is part of a group of symbols ("Structured Append"), this parameter contains (1) the index of the symbol in the group, (2) the number of symbols that belong to the group, and (3) a number that serves as a group identifier. For Aztec Codes the group identifier is a string. If the symbol is not part of a group of symbols ("Structured Append") a empty tuple is returned in case of Aztec Codes.

'gs1_lint_passed': If the symbol contains a GS1 formatted string and the data code model was created to read GS1 codes, additional linting can be performed on the contained string. *'gs1_lint_passed'* will return *'true'*, if this is successful. Otherwise, *'false'* is returned. Linting checks that

- one AI (Application Identifier) does not occur multiple times with different contents,
- AIs required by other AIs are contained,
- AIs excluded by other AIs are not included, and that
- specific formatting rules for AIs are respected.

'gs1_lint_result': *'gs1_lint_result'* performs the linting tests documented in *'gs1_lint_passed'*. If the linting fails, a list of human-readable error messages is returned, if it is successful, *'ok'* is returned.

- DotCode:

DotCodes are able to encode separate data messages in one single DotCode symbol. According to the AIM International Symbology Specification for DotCode, such separated messages should be treated as if they come from different symbols. In the following list, all results are listed which can be queried for DotCodes and need a dedicated result for each separated message segment. They are all postfixed with *'_separated'*.

They return a tuple with the results separated for each separated message segment. In case of a symbol with separated messages the correspondent results without *'_separated'* postfix returns the result for the first separated message segment. Note: If one of the separated messages can not be decoded, no results are returned.

'symbology_ident_separated': see *'symbology_ident'* for details.

'decoded_string_separated': see *'decoded_string'* for details.

'structured_append_separated': see *'structured_append'* for details.

'reader_programming_separated': see *'reader_programming'* for details.

'decoded_data_separated': see *'decoded_data'* for details.

'segment_num': Number of separated message segments.

Status message

The status parameter that can be queried for all candidates reveals why and where in the evaluation phase a candidate was discarded. The following list shows the most important status messages in the order of their generation during the evaluation phase:

- Data matrix ECC 200:

'aborted: too close to image border': The symbol candidate is too close to the border. Only symbols that are completely within the image can be read.

'aborted adjusting: ...': It is not possible to determine the exact position of the finder pattern in the processing image.

'aborted finder pattern: ...': It is not possible to determine the width of one of the two legs of the L-shaped finder pattern.

'aborted leg widths: widths of the finder pattern legs differ too much': The widths of the two legs of the L-shaped finder pattern differ too much.

'aborted alternating side: ...': For one dimension of the candidate, two opposite borders were found during the symbol search phase. However, it is not possible to determine which is the alternating and which the solid side of the finder pattern.

'aborted border search: ...': For one dimension of the candidate, only the border that belongs to the solid side of the finder pattern was found during the symbol search phase. Searching the opposite (the alternating) side failed.

'aborted symbol: invalid size': The number of rows and columns of the symbol that was deduced from the alternating pattern does not yield in a valid ECC 200 code.

'aborted symbol: size does not fit strict model definition': Although the deduced symbol size is a valid ECC 200 size, it is not inside the range predefined by the model.

'aborted symbol: rectangular symbol does not fit strict mirror definition of model': The symbol was identified as a rectangular ECC 200 code. In conjunction with the mirroring parameter of the model, however, the symbol's rows and columns are swapped such that no valid ECC 200 code is achieved. This test is of course not possible for square symbols. There, a wrong mirroring specification will affect the reading of the symbol data and, in general, lead to the following error:

'error correction failed': The error correction failed because there are too many modules that couldn't be interpreted correctly. Normally, this indicates that the print and/or image quality is too bad, but it may also be provoked by a wrong mirroring specification in the model.

'decoding failed: special decoding reader requested': The decoded data contains a message for programming the data code reader. This feature is not supported.

'decoding failed: inconsistent data': The data coded in the symbol is not consistent and therefore cannot be read.

'decoding failed: invalid GS1 format': The data encoded in the symbol is not conform to the GS1 General Specifications. This indicates an attempt to read a non-GS1 symbol with a data code model created as GS1 reader.

'quiet zone is missing': The quiet zone of this candidate is missing or shows severe defects.

'invalid finder pattern or quiet zone check failed': The candidate could be decoded, but was discarded as possible false positive, because the finder pattern or quiet zone could not be found. This additional check is performed for symbols of size 10x10, 12x12 and 8x18, as these codes have little error correction and false positives may easily be found in unrelated texture.

- Data matrix ECC 200 (if a high finder pattern tolerance is chosen, the following messages may occur additionally):
 - '*aborted module grid search: no regular module grid found*': No regular module grid structure could be found within the candidate region. Therefore, the candidate is assumed to be no ECC 200 symbol.
 - '*aborted border search: overlap with previous result*': The current candidate overlaps with a previously found result. Therefore, the search for a valid border was aborted.
 - '*aborted border search: no consistent border found*': No consistent border that leads to a symbol size that is within the range of valid symbol sizes leads to a successful decoding.
 - '*aborted reading: result is likely to be random*': The candidate could be decoded. However, because the symbol size was small and the code had too many decoding errors, the result is very likely to be random, and hence was rejected. This heuristic is applied for symbols of size 10×10 with at least 1 decoding error and for symbols of size 12×12 or 8×18 with more than 1 decoding error.
- QR Code:
 - '*aborted: too close to image border*': The symbol candidate is too close to the border. Only symbols that are completely within the image can be read.
 - '*aborted adjusting: finder patterns*': It is not possible to determine the exact position of the finder pattern in the processing image.
 - '*aborted symbol: different number of rows and columns*': It is not possible to determine for both dimensions a consistent symbol size by the size and the position of the detected finder pattern. When reading Model 2 symbols, this error may occur only with small symbols ($< \text{version } 7$ or 45×45 modules). For bigger symbols the size is coded within the symbol in the version information region. The estimated size is used only as a hint for finding the version information region.
 - '*aborted symbol: invalid size*': The size determined by the size and the position of the detected finder pattern is too small or (only Model 1) too big.
 - '*decoding of version information failed*': While processing a Model 2 symbol, the symbol version as determined by the finder pattern is at least 7 ($\geq 45 \times 45$ modules). However, reading the version from the appropriate region in the symbol failed.
 - '*aborted symbol: size does not fit strict model definition*': Although the deduced symbol size is valid, it is not inside the range predefined by the model.
 - '*decoding of format information failed*': Reading the format information (mask pattern and error correction level) from the appropriate region in the symbol failed.
 - '*error correction failed*': The error correction failed because there are too many modules that couldn't be interpreted correctly. Normally, this indicates that the print and/or image quality is too bad, but it may also be provoked by a wrong mirroring specification in the model.
 - '*decoding failed: inconsistent data*': The data coded in the symbol is not consistent and therefore cannot be read.
 - '*decoding failed: invalid GS1 format*': The data encoded in the symbol is not conform to the GS1 General Specifications. This indicates an attempt to read a non-GS1 symbol with a data code model created as GS1 reader.
- Aztec Code:
 - '*aborted: too close to image border*': The symbol candidate is too close to the border or even partially outside the image.
 - '*aborted: mode message could not be decoded*': The mode message of this candidate could not be decoded because there are too many modules that could not be interpreted correctly.
 - '*aborted: symbol expansion failed*': The expansion of the candidate failed. Most likely because of too heavy perspective distortions.
 - '*aborted symbol: size does not fit strict model definition*': Although the deduced symbol size is valid, it is not inside the range predefined by the model. Adapt the model ([set_data_code_2d_param](#)) to include this candidate in the final results.
 - '*aborted symbol: rectangular symbol does not fit strict mirror definition of model*': Although this candidate is valid, it does not fit the mirroring constraint predefined by the model. Adapt the model ([set_data_code_2d_param](#)) to include this candidate in the final results.
 - '*aborted symbol: invalid format*': Although this candidate is valid, it does not fit the format predefined by the model. Adapt the model ([set_data_code_2d_param](#)) to include this candidate in the final results.

'error correction failed': The error correction failed because there are too many modules that could not be interpreted correctly. Normally, this indicates that the print and/or image quality is too bad, but it may also be provoked by a wrong mirroring specification in the model.

'decoding failed: invalid GS1 format': The data encoded in the symbol is not conform to the GS1 General Specifications. This indicates an attempt to read a non-GS1 symbol with a data code model created as GS1 reader.

- PDF417:

'aborted: too close to image border': The symbol candidate is too close to the border. Only symbols that are completely within the image can be read.

'aborted symbol: size does not fit strict model definition': Although the deduced symbol size is valid, it is not inside the range predefined by the model.

'error correction failed': The error correction failed because there are too many modules that couldn't be interpreted correctly. Normally, this indicates that the print and/or image quality is too bad, but it may also be provoked by a wrong mirroring specification in the model.

'decoding failed: special decoding reader requested': The decoded data contains a message for programming the data code reader. This feature is not supported.

'decoding failed: inconsistent data': The data coded in the symbol is not consistent and therefore cannot be read.

- DotCode:

'aborted module grid search: no regular module grid found' No regular module grid structure could be found within the candidate region. Therefore, the candidate is assumed to be no DotCode symbol.

'aborted symbol: size does not fit strict model definition': Although the deduced symbol size is a valid DotCode size, it is not inside the range predefined by the model.

'error correction failed': The error correction failed because there are too many modules that couldn't be interpreted correctly. Normally, this indicates that the print and/or image quality is too bad, but it may also be provoked by a wrong mirroring specification in the model.

'decoding failed: inconsistent data': The data coded in the symbol is not consistent and therefore cannot be read.

'unmasking: invalid mask type': The first two bits of each DotCode encoded in the data stream of the code determine the so-called mask. The mask is used during encoding process in order to increase graphical robustness. Possible values are 0, 1, 2 and 3. If any other value is encoded in the first two bits, the candidate is marked with this status.

'quiet zone is missing': The quiet zone of this candidate is missing or shows severe defects.

'decoding failed: invalid GS1 format': The data encoded in the symbol is not conform to the GS1 General Specifications. This indicates an attempt to read a non-GS1 symbol with a data code model created as GS1 reader.

While processing a candidate, it is possible that internally several iterations for reading the symbol are performed. If all attempts fail, normally the last abortion state is stored in the candidate structure. E.g., if the QR Code model enables symbols with Model 1 and Model 2 specification, `find_data_code_2d` tries first to interpret the symbol as Model 2 type. If this fails, Model 1 interpretation is performed. If this also fails, the status variable is set to the latest failure state of the Model 1 interpretation. In order to get the error state of the Model 2 branch, the *'model_type'* parameter of the data code model must be restricted accordingly (with `set_data_code_2d_param`).

Parameters

▷ **DataCodeHandle** (input_control) datacode_2d $\leadsto$ handle
Handle of the 2D data code model.

▷ **CandidateHandle** (input_control) integer $\leadsto$ string / integer
Handle of the 2D data code candidate. Either an integer (usually the ResultHandle of `find_data_code_2d`) or a string representing a group of candidates.

Default: 'all_candidates'

Suggested values: CandidateHandle $\in$ {0, 1, 2, 'general', 'all_candidates', 'all_results', 'all_undecoded', 'all_aborted'}

- ▷ **ResultNames** (input_control) attribute.name(-array) $\leadsto$ *string*
Names of the results of the 2D data code to return.
Default: 'status'
List of values: ResultNames $\in$ {'min_search_level', 'max_search_level', 'pass_num', 'result_num', 'candidate_num', 'undecoded_num', 'aborted_num', 'handle', 'pass', 'status', 'search_level', 'process_level', 'polarity', 'module_gap', 'mirrored', 'model_type', 'symbol_rows', 'symbol_cols', 'symbol_size', 'version', 'module_height', 'module_width', 'small_modules_robustness', 'module_aspect', 'slant', 'contrast', 'module_grid', 'decoded_string', 'decoding_error', 'symbology_ident', 'mask_pattern_ref', 'finder_pattern_tolerance', 'contrast_tolerance', 'error_correction_level', 'bin_module_data', 'raw_coded_data', 'corr_coded_data', 'decoded_data', 'gs1_lint_passed', 'gs1_lint_result', 'quality_isoiec15415', 'quality_isoiec15415_labels', 'quality_isoiec15415_values', 'quality_isoiec15415_float_grades', 'quality_isoiec15415_reflectance_margin_module_grades', 'quality_isoiec15415_rows', 'quality_isoiec15415_cols', 'quality_isoiec15415_additional_reflectance_check', 'quality_aimdpm_1_2006', 'quality_aimdpm_1_2006_labels', 'quality_aimdpm_1_2006_values', 'quality_aimdpm_1_2006_reflectance_margin_module_grades', 'quality_aimdpm_1_2006_rows', 'quality_aimdpm_1_2006_cols', 'quality_isoiec29158', 'quality_isoiec29158_labels', 'quality_isoiec29158_values', 'quality_isoiec29158_reflectance_margin_module_grades', 'quality_isoiec29158_reflectance_margin_module_float_grades', 'quality_isoiec29158_rows', 'quality_isoiec29158_cols', 'quality_isoiec29158_float_grades', 'quality_isoiec15415_intermediate', 'quality_isoiec15415_intermediate_labels', 'quality_isoiec15415_intermediate_values', 'quality_aimdpm_1_2006_intermediate', 'quality_aimdpm_1_2006_intermediate_labels', 'quality_aimdpm_1_2006_intermediate_values', 'quality_isoiec29158_intermediate', 'quality_isoiec29158_intermediate_labels', 'quality_isoiec29158_intermediate_values', 'quality_semi_t10_values', 'quality_semi_t10_labels', 'structured_append', 'macro_exist', 'macro_segment_index', 'macro_file_id', 'macro_segment_count', 'macro_time_stamp', 'macro_checksum', 'macro_last_symbol', 'reader_programming', 'aborted', 'orientation', 'layer_num', 'codeword_num', 'format', 'symbology_ident_separated', 'decoded_string_separated', 'structured_append_separated', 'reader_programming_separated', 'decoded_data_separated', 'segment_num'}
- ▷ **ResultValues** (output_control) attribute.value(-array) $\leadsto$ *string* / *integer* / *real*
List with the results.

Example

```
* Example demonstrating how to access the results of the data code search.

* Create a model for reading Data matrix ECC 200 codes
create_data_code_2d_model ('Data Matrix ECC 200', [], [], DataCodeHandle)
* Read an image
read_image (Image, 'datacode/ecc200/ecc200_cpu_010')
* Read the symbol in the image
find_data_code_2d (Image, SymbolXLDs, DataCodeHandle, [], [], \
                  ResultHandles, DecodedDataStrings)

* Get the number of passes
get_data_code_2d_results (DataCodeHandle, 'general', 'pass_num', Passes)

* Get a tuple with the status of all candidates
get_data_code_2d_results (DataCodeHandle, 'all_candidates', 'status', \
                          AllStatus)
* Get the handles of all candidates that were detected as a symbol but
* could not be read
get_data_code_2d_results (DataCodeHandle, 'all_undecoded', 'handle', \
                          HandlesUndecoded)

* For every undecoded symbol, get the contour, the symbol size, and
* the binary module data
dev_set_color ('red')
for i := 0 to |HandlesUndecoded| - 1 by 1
    * Get the contour of the symbol
```

```

get_data_code_2d_objects (SymbolXLD, DataCodeHandle, \
                          HandlesUndecoded[i], 'candidate_xld')

* Get the symbol size
get_data_code_2d_results (DataCodeHandle, HandlesUndecoded[i], \
                          ['symbol_rows','symbol_cols'], SymbolSize)

* Get the binary module data (has to be queried exclusively)
get_data_code_2d_results (DataCodeHandle, HandlesUndecoded[i], \
                          'bin_module_data', BinModuleData)

* Stop for inspecting the data
stop ()
endifor

* Clear the model
clear_data_code_2d_model (DataCodeHandle)

```

Result

The operator `get_data_code_2d_results` returns the value 2 (`H_MSG_TRUE`) if the given parameters are correct and the requested results are available for the last symbol search. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Data Code

```
query_data_code_2d_params ( : : DataCodeHandle,
    QueryName : GenParamName )
```

Get for a given 2D data code model the names of the generic parameters or objects that can be used in the other 2D data code operators.

The operator `query_data_code_2d_params` returns the names of the generic parameters that are supported by the 2D data code operators `set_data_code_2d_param`, `get_data_code_2d_param`, `find_data_code_2d`, `get_data_code_2d_results`, and `get_data_code_2d_objects`.

For an explanation of the concept of the 2D data code reader see the introduction of chapter [Identification / Data Code](#).

The parameter `QueryName` is used to select the desired **parameter group**:

'*get_model_params*': `get_data_code_2d_param` – Parameters for querying the 2D data code model.

'*set_model_params*': `set_data_code_2d_param` – Parameters for adjusting the 2D data code model.

'*find_params*': `find_data_code_2d` – Parameters used while searching and reading the 2D data code symbols.

'*get_result_params*': `get_data_code_2d_results` – Parameters for querying the alphanumeric results of the symbol search.

'*get_result_objects*': `get_data_code_2d_objects` – Parameters for accessing the iconic objects of the symbol search.

'*trained*': `set_data_code_2d_param` – Parameters which values were determined by training. The next training will not reset these parameters, but extend them.

The returned parameter list depends only on the type of the data code and not on the current state of the model or its results.

Parameters

- ▷ **DataCodeHandle** (input_control) datacode_2d $\leadsto$ *handle*
Handle of the 2D data code model.
- ▷ **QueryName** (input_control) attribute.name $\leadsto$ *string*
Name of the parameter group.
Default: 'get_result_params'
List of values: QueryName $\in$ {'get_model_params', 'set_model_params', 'find_params', 'get_result_params', 'get_result_objects', 'trained'}
- ▷ **GenParamName** (output_control) attribute.value-array $\leadsto$ *string*
List containing the names of the supported generic parameters.

Example

* This example demonstrates how the names of all available model parameters
* can be queried. This is used to request first the settings of the
* untrained and then the settings of the trained model.

```
* Create a model for reading Data matrix ECC 200 codes
create_data_code_2d_model ('Data Matrix ECC 200', [], [], DataCodeHandle)
* Query all the names of the generic parameters that can be passed to the
* operator get_data_code_2d_param to request the model
query_data_code_2d_params (DataCodeHandle, 'get_model_params', GenParamName)
* Request the current settings of the (untrained) model
get_data_code_2d_param(DataCodeHandle, GenParamName, ModelParams)
```

```
* Read a training image
read_image (Image, 'datacode/ecc200/ecc200_cpu_007')
* train the model with the symbol in the image
find_data_code_2d (Image, SymbolXLDs, DataCodeHandle, 'train', 'all', \
    ResultHandles, DecodedDataStrings)
* Request the current settings of the (now trained) model
```

```

get_data_code_2d_param(DataCodeHandle, GenParamName, TrainedModelParams)
* Create a tuple that demonstrates the changings
ModelAdaption := GenParamName + ': ' + ModelParams + ' -> ' + \
    TrainedModelParams

* Clear the model
clear_data_code_2d_model (DataCodeHandle)

```

Result

The operator `query_data_code_2d_params` returns the value 2 (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_data_code_2d_model`

Possible Successors

`get_data_code_2d_param`, `get_data_code_2d_results`, `get_data_code_2d_objects`

Module

Data Code

read_data_code_2d_model (: : FileName : DataCodeHandle)
--

Read a 2D data code model from a file and create a new model.

The operator `read_data_code_2d_model` reads the 2D data code model file `FileName` and creates a new model that is an identical copy of the saved model. The parameter `DataCodeHandle` returns the handle of the new model. The model file `FileName` must be created by the operator `write_data_code_2d_model`. The default HALCON file extension for the 2D data code model is 'dcm'.

For an explanation of the concept of the 2D data code reader see the introduction of chapter [Identification / Data Code](#).

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ string
Name of the 2D data code model file.
Default: 'data_code_model.dcm'
File extension: .dcm
- ▷ **DataCodeHandle** (output_control)datacode_2d $\leadsto$ handle
Handle of the created 2D data code model.

Example

```

* This example demonstrates how a model that was saved in an earlier
* session can be used again by reading the model file

* Create a model by reading by reading a data code model file
read_data_code_2d_model ('ecc200_trained_model.dcm', DataCodeHandle)
* Read a symbol image
read_image (Image, 'datacode/ecc200/ecc200_cpu_010')
* Read the symbol in the image
find_data_code_2d (Image, SymbolXLDs, DataCodeHandle, [], [], \
    ResultHandles, DecodedDataStrings)
* Clear the model
clear_data_code_2d_model (DataCodeHandle)

```

Result

The operator `read_data_code_2d_model` returns the value 2 (`H_MSG_TRUE`) if the named 2D data code file was found and correctly read. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Data Code

<code>serialize_data_code_2d_model</code> (: : <code>DataCodeHandle</code> : <code>SerializedItemHandle</code>)

Serialize a 2D data code model.

`serialize_data_code_2d_model` serializes a 2D data code model (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The same data that is written in a file by [write_data_code_2d_model](#) is converted to a serialized item. The 2D data code model is defined by the handle `DataCodeHandle`. The serialized 2D data code model is returned by the handle `SerializedItemHandle` and can be deserialized by [deserialize_data_code_2d_model](#).

For an explanation of the concept of the 2D data code reader see the introduction of chapter [Identification / Data Code](#).

Parameters

- ▷ **`DataCodeHandle`** (`input_control`) `datacode_2d` $\leadsto$ *handle*
Handle of the 2D data code model.
- ▷ **`SerializedItemHandle`** (`output_control`) `serialized_item` $\leadsto$ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_data_code_2d_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

[create_data_code_2d_model](#), [set_data_code_2d_param](#), [find_data_code_2d](#)

Module

Data Code

```
set_data_code_2d_param ( : : DataCodeHandle, GenParamName,
                        GenParamValue : )
```

Set selected parameters of the 2D data code model.

The operator `set_data_code_2d_param` is used to set or change the different parameters of a 2D data code model in order to adapt the model to a particular symbol appearance. All parameters can also be set while creating a 2D data code model with [create_data_code_2d_model](#). The current configuration of the data code model can be queried with [get_data_code_2d_param](#). A list with the names of all parameters that can be set for the given 2D data code type is returned by [query_data_code_2d_params](#).

For an explanation of the concept of the 2D data code reader see the introduction of chapter [Identification / Data Code](#).

Note that the symbol structure of GS1 DataMatrix, GS1 QR Code, GS1 Aztec Code, and GS1 DotCode is identical to the structure of Data Matrix ECC 200, QR Code, Aztec Code, and DotCode, respectively. Therefore, all symbol-ology specific parameters applying to Data Matrix ECC 200, QR Code, Aztec Code, or DotCode apply to their corresponding GS1 variant as well. In the following, the explicit enumeration of the parameters for any particular GS1 code is omitted for sake of readability. Instead, the relevant parameters names are to be inferred from the parameters for the corresponding non-GS1 code type or can be explicitly queried by [query_data_code_2d_params](#) with parameter `'set_model_params'`.

The following overview lists the different generic parameters with the respective value ranges and default values in standard mode (`'standard_recognition'`). If the default values in enhanced mode (`'enhanced_recognition'`) differ from those in the standard mode, they are listed additionally. The same holds, if the default values in the maximum mode `'maximum_recognition'` differ from those in the enhanced mode:

Basic default settings:

- All data code types:

`'default_parameters'`: Reset all model parameters to one of the three basic default settings *standard*, *enhanced*, or *maximum* (see the following summary and [create_data_code_2d_model](#)). In addition to the parameter values, the training state of the model is reset. *Values:* `'standard_recognition'`, `'enhanced_recognition'`, `'maximum_recognition'`
Default: `'standard_recognition'`

Attention: If this parameter is set together with a list of other parameters, this parameter must be at the first position.

`'trained'`: Set for the given parameters the training state to trained. The next training will not overwrite this parameters. If necessary only the parameter range is extended to cover the already trained symbols. For all possible parameters which can be trained see [find_data_code_2d](#). With `'all'` the training state of all trainable parameters is set to trained.

Size and shape of the symbol:

- Data matrix ECC 200 (including the finder pattern):

Attention: After calling `set_data_code_2d_param` to change size or shape of the symbol, the parameters are evaluated in the given order. After each parameter, the consistency of the current settings is checked, and if necessary the current settings are adjusted. Therefore the order in which the changes are done may influence the final setting.

`'symbol_cols_min'`: Minimum number of module columns in the symbol.

Value range: `[10, 12, 14, ... 144]`

Attention: Changing `'symbol_cols_min'` sets `'symbol_shape'` to `'any'`. If the size of the current symbol is only consistent with one shape type `'symbol_shape'` is restricted to `'rectangle'` or `'square'`.

Default: `10`

'symbol_cols_max': Maximum number of module columns in the symbol.

Value range: [10, 12, 14, ... 144]

Attention: Changing 'symbol_cols_max' sets 'symbol_shape' to 'any'. If the size of the current symbol is only consistent with one shape type 'symbol_shape' is restricted to 'rectangle' or 'square'.

Default: 144

'symbol_rows_min': Minimum number of module rows in the symbol.

Value range: [8, 10, 12, ... 144]

Attention: Changing 'symbol_rows_min' sets 'symbol_shape' to 'any'. If the size of the current symbol is only consistent with one shape type 'symbol_shape' is restricted to 'rectangle' or 'square'.

Default: 8

'symbol_rows_max': Maximum number of module rows in the symbol.

Value range: [8, 10, 12, ... 144]

Attention: Changing 'symbol_rows_max' sets 'symbol_shape' to 'any'. If the size of the current symbol is only consistent with one shape type 'symbol_shape' is restricted to 'rectangle' or 'square'.

Default: 144

'symbol_cols': Set 'symbol_cols_min' and 'symbol_cols_max' to the given value.

Value range: [10, 12, 14, ... 144]

Attention: Changing 'symbol_cols' sets 'symbol_shape' to 'any'. If the size of the current symbol is only consistent with one shape type 'symbol_shape' is restricted to 'rectangle' or 'square'.

'symbol_rows': Set 'symbol_rows_min' and 'symbol_rows_max' to the given value.

Value range: [8, 10, 12, ... 144]

Attention: Changing 'symbol_rows' sets 'symbol_shape' to 'any'. If the size of the current symbol is only consistent with one shape type 'symbol_shape' is restricted to 'rectangle' or 'square'.

'symbol_shape': Possible restrictions on the module shape ('rectangle' and/or 'square').

Attention: setting the symbol shape all previously made restrictions concerning the symbol size may change. For 'square' the minimum of 'symbol_cols_min' and 'symbol_rows_min' and the maximum of 'symbol_cols_max' and 'symbol_rows_max' will be used. Additional restrictions can be seen in the following table:

symbol_shape	'any'	'rectangle'	'square'
'symbol_cols_min'	>= 10	>= 18	>= 10
'symbol_cols_max'	<= 144	<= 144	<= 144
'symbol_rows_min'	>= 8	>= 8	>= 10
'symbol_rows_max'	<= 144	<= 26	<= 144

Furthermore, if 'symbol_cols_min' is larger than 'symbol_rows_max', the setting for 'symbol_shape' is ignored and its value set to 'rectangle'.

The same search algorithm is used for both shapes if 'finder_pattern_tolerance' is set to 'low'. Thus, 'symbol_shape' has no effect for the symbol search in this case. However, if 'finder_pattern_tolerance' is set to 'high' or 'any', the value of 'symbol_shape' may speed up the symbol search significantly if it is set to 'rectangle' or 'square'.

Values: 'rectangle', 'square', 'any'

'symbol_size_min': Set 'symbol_cols_min' and 'symbol_rows_min' to the given value and 'symbol_shape' to 'square'.

'symbol_size_max': Set 'symbol_cols_max' and 'symbol_rows_max' to the given value and 'symbol_shape' to 'square'.

'symbol_size': Set 'symbol_cols_min', 'symbol_cols_max', 'symbol_rows_min' and 'symbol_rows_max' to the given value and 'symbol_shape' to 'square'.

- QR Code (including the finder pattern):

'model_type': Type of the QR Code model. The old QR Code Model '1' and the newer Model '2' are supported. With the specification 'any' or '0' both models are carried out.

Values: 1, 2, 'any', '0'

Default: 'any'

'version_min': Minimum symbol version. The symbol version is directly linked to the symbol size. Symbols of version 1 are 21×21 modules in size, version 2 = 25×25 modules, etc. up to version 40 = 177×177 modules. The maximum size of Model 1 symbols is 73×73 = version 14.

Value range: [1 ... 40] (Model 1: [1 ... 14])

Default: 1

'version_max': Maximum symbol version.

Value range: [1 ... 40] (Model 1: [1 ... 14])

Default: 40

'version': Set **'version_min'** and **'version_max'** to the same value.

'symbol_size_min': Minimum size of the symbol in modules. This parameter can be used as an alternative to **'version_min'**.

Value range: [21 ... 177] (Model 1: [21 ... 73])

Default: 21

'symbol_size_max': Maximum size of the symbol in modules. This parameter can be used as an alternative to **'version_max'**:

Value range: [21 ... 177] (Model 1: [21 ... 73])

Default: 177

'symbol_size': Set **'symbol_size_min'** and **'symbol_size_max'** to the same value.

- **Micro QR Code:**

'version_min': Minimum symbol version. The symbol version is directly linked to the symbol size. Symbols are between 11×11 (version M1) and 17×17 (version M4) modules in size.

Value range: [1 ... 4]

Default: 1

'version_max': Maximum symbol version.

Value range: [1 ... 4]

Default: 4

'version': Set **'version_min'** and **'version_max'** to the same value.

'symbol_size_min': Minimum size of the symbol in modules. This parameter can be used as an alternative to **'version_min'**.

Value range: [11 ... 17]

Default: 11

'symbol_size_max': Maximum size of the symbol in modules. This parameter can be used as an alternative to **'version_max'**:

Value range: [11 ... 17]

Default: 17

'symbol_size': Set **'symbol_size_min'** and **'symbol_size_max'** to the same value.

- **PDF417:**

'symbol_cols_min': Minimum number of data columns in the symbol in codewords, i.e., excluding the codewords of the start/stop pattern and of the two row indicators.

Value range: [1 ... 30]

Default: 1

'symbol_cols_max': Maximum number of data columns in the symbol in codewords, i.e., excluding the two codewords of the start/stop pattern and of the two indicators.

Value range: [1 ... 30]

Default: 20 (enhanced: 30)

'symbol_rows_min': Minimum number of module rows in the symbol.

Value range: [3 ... 90]

Default: 5 (enhanced: 3)

'symbol_rows_max': Maximum number of module rows in the symbol.

Value range: [3 ... 90]

Default: 45 (enhanced: 90)

'symbol_cols': Set **'symbol_cols_min'** and **'symbol_cols_max'** to the same value.

'symbol_rows': Set **'symbol_rows_min'** and **'symbol_rows_max'** to the same value.

- **Aztec Code (including the finder pattern):**

'format': Format of the Aztec Code: space separated list with the values **'compact'**, **'full_range'**, or **'rune'**.

Default: **'compact full_range'**

'symbol_size_min': Minimum size of the symbol in modules.

Value range: [11 ... 151]

Default: 11

'symbol_size_max': Maximum size of the symbol in modules.

Value range: [11 ... 151]

Default: 151

'symbol_size': Set *'symbol_size_min'* and *'symbol_size_max'* to the same value.

- **DotCode:** A valid DotCode according to AIM DotCode Revision 4.0-1 consists of one even and one odd dimension. Within HALCON, the column dimension of a DotCode symbol is defined by the reading direction and always refers to the odd dimension.

'symbol_cols_min': Minimum number of module columns in the symbol. Must be odd.

Value range: [5 ... 999]

Default: 5

'symbol_cols_max': Maximum number of module columns in the symbol. Must be odd.

Value range: [5 ... 999]

Default: 999

'symbol_rows_min': Minimum number of module rows in the symbol. Must be even.

Value range: [4 ... 998]

Default: 4

'symbol_rows_max': Maximum number of module rows in the symbol. Must be even.

Value range: [4 ... 998]

Default: 998

'symbol_cols': Set *'symbol_cols_min'* and *'symbol_cols_max'* to the given value. Must be odd.

Value range: [5 ... 999]

'symbol_rows': Set *'symbol_rows_min'* and *'symbol_rows_max'* to the given value. Must be even.

Value range: [4 ... 998]

Appearance of the modules in the image:

- All data code types:

'polarity': Describes the polarity of the symbol in the image, i.e., the parameter determines if the symbol appears light on a dark background or dark on a light background.

Values: *'dark_on_light'*, *'light_on_dark'*, *'any'*.

Default: *'dark_on_light'* (enhanced: *'any'*)

'mirrored': Describes whether the symbol is or may be mirrored (which is equivalent to swapping rows and columns of the symbol).

Values: *'no'*, *'yes'*, *'any'*

Default: *'any'*

- All data code types except Data Matrix ECC 200 and DotCode:

'contrast_min': Minimum contrast between the foreground and the background of the symbol (specified as gray value difference). This measure corresponds with the minimum gradient between the symbol's foreground and the background and is therefore also depending on the image sharpness.

Values: [1 ... 255]

Default: 30 (enhanced: 10)

- All data code types except PDF417:

'module_size_min': Minimum size of the modules in the image in pixels. Please note that for optimal reading performance a module size of at least 3-4 pixels is recommended.

Values: [1 ... 100]

Default: 6 (enhanced: 2, maximum: 1)

For DotCode:

Default: 4 (enhanced, maximum: 2)

'module_size_max': Maximum size of the modules in the image in pixels.

Values: [2 ... 100]

Default: 20 (enhanced: 100)

For DotCode:

Default: 100

'module_size': Set *'module_size_min'* and *'module_size_max'* to the same value.

The gap between modules can be set via the `'module_gap*'` parameters as explained in the following paragraph:

It is possible to specify whether neighboring foreground modules are connected or whether there is or may be a gap between them. If the foreground modules are connected and fill the module space completely, the gap parameter can be set to `'no'`. The parameter is set to `'small'` if there is a very small gap between two modules, i.e., $< 10\%$ of the module size. It can be set to `'big'` if the gap is bigger (in relation to the module size: $< 50\%$). The last two settings may also be useful if the foreground modules – although being connected – appear thinner as their entitled space (e.g., as a result of blooming caused by a bright illuminant). If the foreground modules appear only as very small dots, in general, an appropriate preprocessing of the image for detecting or enlarging the modules will be necessary (e.g., by `gray_erosion_shape` or `gray_dilation_shape`).

`'module_gap_min'`: Minimum gap.

Values: `'no'`, `'small'`, `'big'` (`'big'` is not available for DotCode)

Default: `'no'`

`'module_gap_max'`: Maximum gap.

Values: `'no'`, `'small'`, `'big'`

Default (Data Matrix ECC 200): `'no'` (enhanced: `'small'`, maximum: `'big'`)

Default (DotCode): `'no'` (enhanced: `'small'`, maximum: `'small'`)

Default (Aztec Code, Micro QR Code, QR Code): `'small'` (enhanced: `'big'`)

`'module_gap'`: Set `'module_gap_min'` and `'module_gap_max'` to the same value.

- All data code types except DotCode:

`'small_modules_robustness'`: Robustness of the decoding of data codes with very small module sizes. Setting the parameter `'small_modules_robustness'` to `'high'` increases the likelihood of being able to decode data codes with very small module sizes. Additionally, in that case the minimum module size should also be adapted accordingly, thus `'module_size_min'` and `'module_width_min'` (PDF417) should be set to the expected minimum module size and width, respectively. Setting `'small_modules_robustness'` to `'high'` can significantly increase the internal memory usage of `find_data_code_2d`. Thus, in the default case `'small_modules_robustness'` should be set to `'low'`. If `'small_modules_robustness'` is set to `'high'` the maximal accepted image size is bisected (see `get_system 'halcon_xl'`).

Values: `'low'`, `'high'`

Default: `'low'` (enhanced: `'low'`, maximum: `'high'`)

- PDF417:

`'module_width_min'`: Minimum module width in the image in pixels.

Values: `[1 ... 100]`

Default: 3 (enhanced: 2, maximum: 1)

`'module_width_max'`: Maximum module width in the image in pixels.

Values: `[2 ... 100]`

Default: 15 (enhanced: 100)

`'module_width'`: Set `'module_width_min'` and `'module_width_max'` to the same value.

`'module_aspect_min'`: Minimum module aspect ratio (module height to module width).

Values: `[0.5 ... 20.0]`

Default: 1.0

`'module_aspect_max'`: Maximum module aspect ratio (module height to module width).

Values: `[0.5 ... 20.0]`

Default: 4.0 (enhanced: 10.0)

`'module_aspect'`: Set `'module_aspect_min'` and `'module_aspect_max'` to the same value.

- Data Matrix ECC 200:

`'slant_max'`: Maximum deviation of the angle of the L-shaped finder pattern from the (ideal) right angle (the angle is specified in radians and corresponds to the distortion that occurs when the symbol is printed or during the image acquisition).

Value range: `[0.0 ... 0.5235]`

Default: $0.1745 = 10^\circ$ (enhanced: $0.5235 = 30^\circ$)

`'finder_pattern_tolerance'`: Tolerance of the search with respect to a defect or partially occluded finder pattern. The finder pattern includes the L-shaped side as well as the opposite alternating side. Dependent on this parameter, different algorithms are used during the symbol search in `find_data_code_2d`. In

one case ('low'), it is assumed that the finder pattern is present to a high degree and shows almost no disturbances. In the other case ('high'), the finder pattern may be defect or partially occluded without influencing the recognition and the reading of the symbol. Note, however, that in this mode the parameters for the symbol search should be restricted as narrow as possible by using `set_data_code_2d_param` because otherwise the run-time of `find_data_code_2d` may significantly increase. Also note that the two algorithms slightly differ from each other in terms of robustness. This may lead to different results depending on the value of '`finder_pattern_tolerance`' even if the finder pattern of the symbol is not disturbed. For example, if 'high' is chosen, only symbols with an equidistant module grid can be found (see below), and hence the robustness to perspective distortions is decreased. Finally, if '`finder_pattern_tolerance`' is set to 'any' both algorithms are applied.

Values: 'low', 'high', 'any'

Default: 'low' (enhanced: 'low', maximum: 'any')

'contrast_tolerance': Describes the tolerance of the search with respect to local contrast variations (e.g., in the presence of glare or reflections). Depending on the value of the parameter two different algorithms are applied. If '`contrast_tolerance`' is set to 'high' the robustness in the presence of strong local contrast variations is improved. In the case where '`contrast_tolerance`' is set to 'low' the algorithm less robust in case of strong local contrast variations, however it is faster and still able to handle contrast variations under normal circumstances and therefore should be used in most cases. If '`contrast_tolerance`' is set to 'any' both algorithms are applied.

Values: 'low', 'high', 'any'

Default: 'low' (enhanced: 'low', maximum: 'any')

'module_grid': Describes whether the size of the modules may vary (in a specific range) or not. Dependent on this parameter different algorithms are used for calculating the module's center positions. If it is set to 'fixed', an equidistant grid is used. Allowing a variable module size ('variable'), the grid is aligned only to the alternating side of the finder pattern. With 'any' both approaches are tested one after the other. Please note that the value of '`module_grid`' is ignored if '`finder_pattern_tolerance`' is set to 'high'. In this case an equidistant grid is assumed.

Values: 'fixed', 'variable', 'any'

Default: 'fixed' (enhanced: 'any')

- QR Code:

'position_pattern_min': Number of position detection patterns that have to be visible for generating a new symbol candidate.

Value range: [2, 3]

Default: 3 (enhanced: 2)

- Aztec Code:

'finder_pattern_tolerance': Tolerance of the search with respect to a defect or partially occluded finder pattern. Depending on this parameter, different algorithms are used during the symbol search in `find_data_code_2d`. In one case ('low'), it is assumed that all rings of the finder pattern can be extracted. In the other case ('high') it is assumed that at least one of the rings of the finder pattern can be extracted. As a consequence the runtime of the reader increases, if this parameter is set to 'high'.

Values: 'low', 'high'

Default: 'low' (enhanced: 'high')

'additional_levels': To increase the robustness of the Aztec Code reader, a number of additional search levels (in addition to the search levels derived from the minimum and maximum module dimensions) can be specified via this parameter. Be aware that this increases the runtime of the reader, especially if no code is found.

Value range: [0 ... 2]

Default: 0

General model behavior:

- All data code types:

'persistence': Controls whether certain intermediate results of the symbol search with `find_data_code_2d` are stored temporarily or persistently in the model. The memory requirements of `find_data_code_2d` are significantly smaller if the data is stored temporarily (default). On the other hand, by using the persistent storage it is possible to access some of the data for debugging reasons after searching for symbols, e.g., to investigate why a symbol could not be read. The

memory requirements of `find_data_code_2d` can further be reduced by setting `'persistence'` to `-1` such that only the data necessary for retrieving the decoded data is stored with the model. Be aware that print quality inspection can only be performed for Data Matrix ECC 200 symbols with this setting of `'persistence'`.

Values: `-1` (only decoded data), `0` (temporary), `1` (persistent)

Default: `0`

`'discard_undecoded_candidates'` Controls whether candidates that could not be successfully decoded are stored in the model. Set this parameter to `'yes'` to reduce the amount of memory consumed by the model. Note that in this case information about undecoded candidates cannot be queried by using `get_data_code_2d_objects` or `get_data_code_2d_results`.

Values: `'yes'`, `'no'`

Default: `'no'`

`'strict_model'`: Controls the behavior of `find_data_code_2d` while detecting symbols that could be read but that do not fit the model restrictions on the size of the symbols. They can be rejected (strict model, set to `'yes'`) or returned as a result independent of their size and the size specified in the model (lax model, set to `'no'`). Please note that for DotCode symbols the module size restrictions (`'module_size_min'` and `'module_size_max'`) are not checked even if `'strict_model'` is set to `'yes'`.

Values: `'yes'` (strict), `'no'` (not strict)

Default: `'yes'`

`'string_encoding'`: Sets the expected string encoding of the string that is encoded in the symbol. It's possible to switch between UTF-8, Latin-1, and the string encoding of the current locale. If necessary, the string will be transcoded accordingly. In raw mode, the string will be passed unchanged.

Values: `'utf8'`, `'locale'`, `'latin1'`, `'raw'`

Default: `'latin1'`

`'timeout'`: By the use of this parameter, it is possible to abort `find_data_code_2d` after a defined period in milliseconds. This is especially useful in cases where a maximum cycle time has to be ensured. All results gained before the timeout can be accessed by `get_data_code_2d_results`. Passing values less or equal zero implies a deactivation of the timeout (default).

The temporal accuracy is about 10 ms. It depends on several factors including the speed of your computer, the image size and the `'timer_mode'` set via `set_system`.

`find_data_code_2d` does not raise an exception if a timeout occurs. To check whether `find_data_code_2d` has been interrupted, check the parameter `'aborted'` in `get_data_code_2d_results`.

Note that the timeout is ignored if `find_data_code_2d` runs in training mode.

Typical values: `'false'`, `-1`, `20 ... 100`

Default: `'false'`

`'abort'`: Using this option, it is possible to abort `find_data_code_2d` from another thread. When `set_data_code_2d_param` is called with `'abort'`, an instance of `find_data_code_2d` with the model `DataCodeHandle` running in another thread is requested to abort. If there is no `find_data_code_2d` running with this model, nothing happens.

The operator `find_data_code_2d` might not return immediately. It has to reach a cancellation point to ensure a proper cleanup. Depending on different factors like the computer performance this may take up to 10 ms.

All decoded results until this moment, are still returned. Note that the parameter is ignored if `find_data_code_2d` runs in training mode.

Note: This is the only action with a data code handle, which can be used from different threads without requiring additional synchronization.

Default: `'true'` (The value is not processed.)

- All data code types except Aztec Code:

`'strict_quiet_zone'`: Controls the behavior of `find_data_code_2d` while detecting symbols that could be read but show defects in their quiet zone. If `'strict_quiet_zone'` is set to `'yes'` the quiet zone of all decoded symbol is validated similar to the method used for print quality inspection. Symbols with poor grades for their quiet zone are not returned as a result. Their `'status'` is set to `'quiet zone is missing'`. If `'strict_quiet_zone'` is set to `'no'` (this is the default case), all readable symbols are returned as a result.

Values: `'yes'`, `'no'`

Default: `'no'`

- All data code types except DotCode:

'quality_isoiec15415_aperture_size': The reference image, on which the quality grades Symbol Contrast, Modulation, Reflectance Margin, and Fixed Pattern Damage are assessed, is obtained by applying a synthetic aperture (circular mean filter) on the original image. This parameter determines the filter size as the part of the module size. According to the standard, this value should be chosen between 0.5 and 0.8 depending on the application.

For further guidance on selecting the aperture, see ISO/IEC 15415:2011 Annex D.2.

Value range: [0 ... 1]

Default: 0.8

'quality_isoiec15415_reflectance_reference': The contrast used to assess the quality grade Symbol Contrast is normalized with a reference grayvalue for reflectance. This value can be obtained with barium sulphate or magnesium oxide samples, i.a., see ISO/IEC 15415:2011 section 7.3. *Value range:* [1 ... 255]

Default: 255

'quality_isoiec15415_smallest_module_size': The module size used to determine the size of the synthetic aperture. This can either be a fixed value in pixel or *'adaptive'*. In the later case, the module size obtained by the preceding [find_data_code_2d](#) is used. The final diameter of the filter is given by multiplying *'quality_isoiec15415_aperture_size'* with this size. See ISO/IEC 15415:2011 section 7.3.3.

Value range: ≥ 0

Default: *'adaptive'*

- Data Matrix ECC 200:

'quality_isoiec15415_decode_algorithm': The computation of the quality grades is based on the module grid determined for print quality grading. Use this parameter to choose the algorithm used to obtain this grid.

'robust': Recommended for process control matters in which no calibrated camera and lighting setup based on ISO/IEC 15415:2011 is provided. The returned quality grades as well as the calculation of the grading parameters is in compliance with the international standard ISO/IEC 15415:2011. To compensate for variances caused by the flexibility in hardware setups additional information gathered during decoding of the code as well as assumptions regarding the hardware setups are used to increase the robustness of the quality inspection.

'reference': Recommended for verification of print quality. In compliance with the international standard ISO/IEC 15415:2011 the verification requires a specific camera calibration as well as lighting setup to return standard compliant grading results. In contrast to the standard, we explicitly apply a lower bound of 20% for the relative aperture factor during the computation of the constants *d_min*, *m_min*, and *g_max*. Additionally, if the module size (as determined by the preceding [find_data_code_2d](#) call) drops below 4 pixels, the algorithm cannot be used and all grades are reported as -1. The stated lower bounds help to define a reasonable application window for the reference decoding algorithm. Finally, all grades will be set to -1 if the algorithm fails during the module grid determination.

Default: *'robust'*

'candidate_selection': Controls the selection of candidate regions that are used for symbol detection. Setting this parameter to *'extensive'* increases the number of generated candidate regions and thus the likelihood of detecting a code. However, a higher number of candidates can lead to higher runtimes. If *'candidate_selection'* is set to *'default'*, less candidate regions are used. In most cases this smaller set of candidates is sufficient.

Values: *'default'*, *'extensive'*

Default: *'default'* (enhanced: *'extensive'*)

'decoding_scheme': Controls the decoding step of Data Matrix ECC 200. When setting this to *'raw'*, this allows to read symbols where the appearance and the error correction step conform to ISO/IEC 16022: 2006, but where the encoding is custom. The decoded data are the error corrected data, are retrieved with the *'decoded_data'* parameter of [get_data_code_2d_results](#) and must be further processed by the user.

Values: *'default'*, *'raw'*

Default: *'default'*

- DotCode:

'candidate_selection': Controls the selection of candidate regions that are used for symbol detection. Setting this parameter to *'extensive'* increases the number of generated candidate regions and thus the likelihood of detecting a code. Setting this parameter to *'all'* all possible candidates are used and therefore don't

get filtered based on their probability of being a DotCode. If *'candidate_selection'* is set to *'default'*, less candidate regions are used.

Values: *'default'*, *'extensive'*, *'all'*

Default: *'default'* (enhanced: *'extensive'*, maximum: *'all'*)

'max_allowed_error_correction': Controls the maximum allowed error correction. Due to the high error correction capacity, it is possible to successfully decode false positive DotCode candidates. Especially candidates which only cover a small part of a real DotCode may be decoded successfully because of the error correction capabilities. This is the case because DotCode symbols can consist of almost every size. So there are fewer criteria to decide whether the candidate is valid or not. In order to tackle this problem, the parameter *'max_allowed_error_correction'* can be used to specify the percentage of maximum allowed error correction. Per default the value is set to *'0.9'*, which means 90%. This choice helps to reduce the number of false reads without any significant impact on the number of correct decodes. Setting the value to e.g., *'0.5'* means, only candidates which could be decoded with maximum 50% used error correction, will be returned as successfully decoded results.

Value range: *[0.0 ... 1.0]*

Default: *'0.9'*

When setting the model parameters, **attention** should be paid especially to the following issues:

- Symbols whose size does not comply with the size restrictions made in the model (with the generic parameters *'symbol_rows*'*, *'symbol_cols*'*, *'symbol_size*'*, or *'version*'*) will not be read if *'strict_model'* is set to *'yes'*, which is the default. This behavior is useful if symbols of a specific size have to be detected while other symbols should be ignored. On the other hand, neglecting this parameter can lead to problems, e.g., if one symbol of an image sequence is used to adjust the model (including the symbol size), but later in the application the symbol size varies, which is quite common in practice.
- The run-time of [find_data_code_2d](#) depends mostly on the following model parameters, namely in cases where the requested number of symbols *cannot* be found in the image: *'polarity'*, *'module_size_min'* (Data Matrix ECC 200, QR Code, and Micro QR Code) and *'module_size_min'* together with *'module_aspect_min'* (PDF417), and if the minimum module size is very small also the parameters *'module_gap_*'* (Data Matrix ECC 200, Aztec Code, QR Code, and Micro QR Code), for QR Code also *'position_pattern_min'*. For Data Matrix ECC 200 symbols, if *'finder_pattern_tolerance'* is set to *'high'* or *'any'*, the symbol size should be restricted with *'symbol_size_min'*, *'symbol_size_max'*, *'symbol_size'*, and *'symbol_shape'* as narrow as possible.

Parameters

▷ **DataCodeHandle** (input_control) *datacode_2d* $\leadsto$ *handle*
Handle of the 2D data code model.

▷ **GenParamName** (input_control) *attribute.name(-array)* $\leadsto$ *string*
Names of the generic parameters that shall be adjusted for the 2D data code.

Default: *'polarity'*

List of values: *GenParamName* $\in$ {*'default_parameters'*, *'strict_model'*, *'persistence'*, *'polarity'*, *'mirrored'*, *'contrast_min'*, *'candidate_selection'*, *'discard_undecoded_candidates'*, *'model_type'*, *'version'*, *'version_min'*, *'version_max'*, *'string_encoding'*, *'symbol_size'*, *'symbol_size_min'*, *'symbol_size_max'*, *'symbol_cols'*, *'symbol_cols_min'*, *'symbol_cols_max'*, *'symbol_rows'*, *'symbol_rows_min'*, *'symbol_rows_max'*, *'symbol_shape'*, *'module_size'*, *'module_size_min'*, *'module_size_max'*, *'small_modules_robustness'*, *'module_width_min'*, *'module_width_max'*, *'module_width'*, *'module_aspect_min'*, *'module_aspect_max'*, *'module_aspect'*, *'module_gap'*, *'module_gap_min'*, *'module_gap_max'*, *'slant_max'*, *'module_grid'*, *'position_pattern_min'*, *'strict_quiet_zone'*, *'abort'*, *'trained'*, *'timeout'*, *'finder_pattern_tolerance'*, *'format'*, *'additional_levels'*, *'contrast_tolerance'*, *'quality_isoiec15415_aperture_size'*, *'quality_isoiec15415_decode_algorithm'*, *'quality_isoiec15415_reflectance_reference'*, *'quality_isoiec15415_smallest_module_size'*, *'decoding_scheme'*, *'max_allowed_error_correction'*}

▷ **GenParamValue** (input_control) *attribute.value(-array)* $\leadsto$ *string* / *integer* / *real*
Values of the generic parameters that are adjusted for the 2D data code.

Default: *'light_on_dark'*

Suggested values: *GenParamValue* $\in$ {*'standard_recognition'*, *'enhanced_recognition'*, *'maximum_recognition'*, *'all'*, *'yes'*, *'no'*, *'any'*, *'dark_on_light'*, *'light_on_dark'*, *'square'*, *'rectangle'*, *'small'*, *'big'*, *'fixed'*, *'variable'*, *'low'*, *'high'*, *'default'*, *'extensive'*, *'utf8'*, *'locale'*, *'raw'*, *'robust'*,

'reference', 0, 1, 2, 3, 4, 5, 6, 7, 8, 10, 30, 50, 70, 90, 12, 14, 16, 18, 20, 22, 24, 26, 32, 36, 40, 44, 48, 52, 64, 72, 80, 88, 96, 104, 120, 132, 144}

Example

```
* This examples shows how a model can be adapted to a specific symbol if
* the symbol parameters are known

* Create a model for reading Data matrix ECC 200 codes
create_data_code_2d_model ('Data Matrix ECC 200', [], [], DataCodeHandle)
* Restrict the model by setting the module size
set_data_code_2d_param (DataCodeHandle, \
                        ['module_size_min', 'module_size_max'], [4, 7])
* Change the polarity setting of the model from 'dark_on_light' to
* 'light_on_dark'
set_data_code_2d_param (DataCodeHandle, 'polarity', \
                        'light_on_dark')

* Read an image
read_image (Image, 'datacode/ecc200/ecc200_cpu_010')
* Read the symbol in the image
find_data_code_2d (Image, SymbolXLDs, DataCodeHandle, [], [], \
                  ResultHandles, DecodedDataStrings)

* Clear the model
clear_data_code_2d_model (DataCodeHandle)
```

Result

The operator `set_data_code_2d_param` returns the value 2 (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `DataCodeHandle`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Data Code

write_data_code_2d_model (: : DataCodeHandle, FileName :)
--

Writes a 2D data code model into a file.

The operator `write_data_code_2d_model` writes a 2D data code model, which was created by `create_data_code_2d_model`, into a file with the name `FileName`. This facilitates creating an identical copy of the saved model in a later session with the operator `read_data_code_2d_model`. The default HALCON file extension for the 2D data code model is 'dcm'. The handle of the model to write is passed in `DataCodeHandle`.

For an explanation of the concept of the 2D data code reader see the introduction of chapter [Identification / Data Code](#).

Parameters

- ▷ **DataCodeHandle** (input_control) `datacode_2d` $\leadsto$ *handle*
Handle of the 2D data code model.
- ▷ **FileName** (input_control) `filename.write` $\leadsto$ *string*
Name of the 2D data code model file.
Default: 'data_code_model.dcm'
File extension: .dcm

Example

```
* This example demonstrates how a trained model can be saved for
* a future session

* Create a model for reading Data matrix ECC 200 codes
create_data_code_2d_model ('Data Matrix ECC 200', [], [], DataCodeHandle)
* Read a training image
read_image (Image, 'datacode/ecc200/ecc200_cpu_007')
* Train the model with the symbol in the image
find_data_code_2d (Image, SymbolXLDs, DataCodeHandle, 'train', 'all', \
                  ResultHandles, DecodedDataStrings)
* Write the model into a file
write_data_code_2d_model (DataCodeHandle, 'ecc200_trained_model.dcm')
* Clear the model
clear_data_code_2d_model (DataCodeHandle)
```

Result

The operator `write_data_code_2d_model` returns the value 2 (`H_MSG_TRUE`) if the passed handle is valid and if the model can be written into the named file. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Chapter 15

Image

This chapter contains operators regarding the handling of images.

In order to understand the different types of images you can process in HALCON, the three components of an image (pixels, channels and domain) are explained in the following paragraphs.

Pixels

In HALCON pixels can be used in order to represent information of various kinds. Therefore different pixel types are distinguished. The following table lists the different pixel types and the corresponding standard image types for images. Note that this list is not exclusive (e.g., a gray value image can be of multiple other image types as well). You can convert the image type using [convert_image_type](#).

Pixel Type	Standard Image Type
Gray Values	byte, uint2
Difference	int1, int2
2D Histogram	int4
Edge Directions	direction
Derivatives	real
Fourier Transform	complex
Hue Values	cyclic
Vector Field	vector_field

Note that the image type `vector_field` can be specified further by using `vector_field_absolute` or `vector_field_relative`. There is also the image type `int8` (64 bits with sign), which is only available on 64 bit systems. Further information on the different pixel types is given below.

Gray Values Gray images are of type `byte` (8 bits without sign) or `uint2` (16 bits without sign) and consist of pixels usually representing local intensities of light on a sensor.

Gray value image.

Difference In order to show the differences between two images e.g., the image types `int1` (8 bits with sign) or `int2` (16 bits with sign) are well suited.

Comparing an image (1) with another (e.g., consecutively taken) one (2) by subtracting the latter from the former results in a difference image (3).

2D Histogram To examine image features based on the occurrence of gray values in two images you can use a 2D histogram, which is of type `int4` (32 bits with sign). Thereby, the axes of the 2D histogram each represent the gray values of an input image. The gray values of corresponding pixels in the input images are registered in the 2D histogram accordingly. The higher the frequency of a specific combination of gray values, the higher the gray value in the output image (see also [histo_2dim](#)).

Two channels ((1), (2)) of an exemplary image and their respective 2D histogram (3).

Edge Directions To represent the orientation of the edge gradient, the image type `direction` (8 bits without sign) is available.

Examining an image (1) by visualizing the orientation of its image edges (2).

For images of type `direction` an edge direction of x degrees in mathematically positive sense and with respect to the horizontal axis is stored as $x / 2$ in the edge direction image (resulting in gray values from 0 to 179). Points with edge amplitude 0 are assigned the edge direction 255 (undefined direction).

Visualizing the edge directions for dark and bright objects using `sobel_dir`. The edge direction (marked with an tangential arrow in the input image) of a pixel is encoded by a corresponding gray value in the result image on the right. Locations without an edge are represented by a gray value of 255.

Derivatives The image type `real` (32 bits floating point value) is used to represent derivatives of an image, e.g., in order to extract edges.

Some features of an image (1) (e.g., edges, gradients) can be examined by considering its derivatives (2).

Fourier Transform To inspect the frequency domain of an image the Fourier transform is used. The combination of magnitude and phase of the frequencies is represented by complex numbers, therefore the image type is complex (two real values per pixel).

One strategy to identify letters (1) is to observe its frequency domain by calculating the Fourier transform (2).

Hue Values Hue values are encoded *cyclic* (8 bits without sign) so that $255 + 1 = 0$.

Pixels representing hue values. When increasing a pixel value beyond 255, it is shifted to the other end of the spectrum. Therefore adding a constant number to each cyclic pixel value of (1) results in an image like (2).

Vector Field A special image type to represent absolute/relative optical flow is `vector_field` (composed by two `real` images for x and y direction). The type of vector field can be specified further by assigning `vector_field_absolute` (interpreted as absolute coordinates) or `vector_field_relative` (interpreted as vectors).

Relative motion of pixels (e.g., in consecutive images (1) and (2)) can be represented in a vector field (3).

Channels

Besides different pixel types, an image can use different image channels in order to store specific information. Basically, you can use channels to assign multiple values to a pixel. The following sections mention a few cases, where different numbers of channels are useful.

Gray Value Images (Single-Channel Images) Often, there is only one value stored for every pixel of an image. A gray value image for example, stores a value representing local light intensity on a sensor for each pixel. Nevertheless, various types of information can be assigned to those pixels (e.g., the derivatives of gray values, distances). Visualizing them analogous to a gray value image can help interpreting the data.

RGB Images (Three-Channel Images) For a colored image, the pixel values are typically stored in three channels each representing the intensity of either red, green or blue light of the respective pixel (RGB image). Through additive mixing of the three values assigned to one pixel, a specific color is defined.

Besides the RGB model there are several further color spaces. For more information about those models and how to transform between the different color spaces see [trans_to_rgb](#) and [trans_from_rgb](#) respectively.

RGB image (1) and its three channels separately: The local intensities differ for red (2), green (3), and blue channel (4).

Multispectral Images (Multi-Channel Images) With special cameras, a variety of spectral bands can be registered in an image, including from outside the visible light spectrum. Satellite cameras, for instance, often acquire multispectral data and store them in multiple distinct channels respectively.

Six channels of an satellite image: the different channels of a multispectral image can be used to extract features that are most prominent in a special spectral band.

Multi-Channel Images Besides representing light intensities, assembling multiple channels in one image can help with various other tasks.

For example, combining a gray value image with an additional channel containing the respective depth values of the image pixels allows you to visualize the scene in a 3D plot.

Instead of using a depth camera you can also use a multi-channel image to extract depth information. Therefore, each channel must contain one of a series of images taken with different focus levels.

Besides containing spacial information, the channels of an image can also be interpreted as a feature space in order to perform a principal components analysis.

Domain

The image domain determines the area of an image that is used in the succeeding operations. In order to focus the processing on regions of interest and/or speed up the operations you can reduce the domain to the relevant parts of an image.

The domain of the original image (1) is reduced, e.g., considering a minimum gray value threshold (2). Areas that are still relevant for further operations (orange) remain in the result image (3), whereas unwanted areas of the image are excluded (black).

15.1 Access

```
get_grayval ( Image : : Row, Column : Grayval )
```

Access the gray values of an image object.

The parameter `Grayval` is a tuple of floating point numbers or integer numbers which returns the gray values of several pixels of `Image`. For a multi-channel image, a group of elements, in particular one value for each channel (or two values for each channel for complex or vector field images), is returned for each pixel. The row coordinates of the pixels are specified in the tuple `Row`, the column coordinates are specified in the tuple `Column`.

Note that `get_grayval` does not take the domain of the image into account, i.e., if the domain has been reduced, e.g., with `reduce_domain`, gray values are returned even for points that lie outside the domain.

Attention

The type of the values of `Grayval` depends on the type of the gray values of the channels of the image `Image`. The operator `get_grayval` produces quite some overhead. Typically, it is used to get single gray values of an image (e.g., `get_mposition` followed by `get_grayval`). It is not suitable for programming image processing operations such as filters. In this case it is more useful to use the operator `get_image_pointer1` and to directly use the C or C++ interface for integrating own procedures.

Parameters

▷ **Image** (input_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Image whose gray value is to be accessed.

- ▷ **Row** (input_control) point.y(-array) $\leadsto$ *integer*
 Row coordinates of pixels to be viewed.
Default: 0
Suggested values: Row $\in$ {0, 64, 128, 256, 512, 1024}
Value range: $0 \leq \text{Row} \leq 32767$ (lin)
Minimum increment: 1
Recommended increment: 1
Restriction: $0 \leq \text{Row} \ \&\& \ \text{Row} < \text{height}(\text{Image})$
- ▷ **Column** (input_control) point.x(-array) $\leadsto$ *integer*
 Column coordinates of pixels to be viewed.
Number of elements: Column == Row
Default: 0
Suggested values: Column $\in$ {0, 64, 128, 256, 512, 1024}
Value range: $0 \leq \text{Column} \leq 32767$ (lin)
Minimum increment: 1
Recommended increment: 1
Restriction: $0 \leq \text{Column} \ \&\& \ \text{Column} < \text{width}(\text{Image})$
- ▷ **Grayval** (output_control) grayval-array $\leadsto$ *real / integer*
 Gray values of indicated pixels.

Result

If the state of the parameters is correct, the operator `get_grayval` returns the value 2 (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`set_grayval`

Module

Foundation

get_grayval_contour_xld (Image, Contour : : Interpolation : Grayval)
--

Return gray values of an image at the positions of an XLD contour.

The operator `get_grayval_contour_xld` returns interpolated gray values at several subpixel positions of the `Image`. The coordinates of the positions are specified via one XLD contour `Contour`. The gray values are returned in `Grayval`.

The interpolation method can be selected via the parameter `Interpolation`:

'nearest_neighbor': The results are the gray values of the nearest pixels to the selected coordinates. For images of type byte, direction, cyclic, uint2, int1, int2, int4, and int8, the parameter `Grayval` is a tuple of integer numbers. For images of type real and complex, the parameter `Grayval` is a tuple of floating point numbers.

'bilinear': The parameter `Grayval` is computed using a bilinear interpolation of the four neighboring gray values of the selected coordinates. The result is a tuple of floating point numbers. The runtime increases significantly compared to **'nearest_neighbor'**. Direction and cyclic images are treated like byte images.

'*bicubic*': The parameter `Grayval` is computed using a bicubic interpolation of sixteen neighboring gray values of the selected coordinates. The result is a tuple of floating point numbers. The runtime increases significantly compared to '*bilinear*'. Direction and cyclic images are treated like byte images. In this mode, the resulting gray values may contain values that lie outside of the range of numbers that can be represented by the input image type.

'*bicubic_clipped*': The parameter `Grayval` is computed using a bicubic interpolation of sixteen neighboring gray values of the selected coordinates. The result is a tuple of floating point numbers. The runtime increases significantly compared to '*bilinear*'. Direction and cyclic images are treated like byte images. In this mode, resulting gray values that lie outside of the range of numbers that can be represented by the input image type are clipped to that range.

Note that `get_grayval_contour_xld` does not take the domain of the image into account, i.e., if the domain has been reduced, e.g., with `reduce_domain`, gray values are returned even for points that lie outside the domain.

Please note also that each point of the XLD contour must be in the range $-0.5 \leq \text{row coordinate} < \text{height}(\text{Image}) - 0.5$ and $-0.5 \leq \text{column coordinate} < \text{width}(\text{Image}) - 0.5$.

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex
Image whose gray values are to be accessed.
- ▷ **Contour** (input_object) xld_cont $\leadsto$ object
Input XLD contour with the coordinates of the positions.
- ▷ **Interpolation** (input_control) string $\leadsto$ string
Interpolation method.
Default: 'nearest_neighbor'
List of values: Interpolation $\in$ {'nearest_neighbor', 'bilinear', 'bicubic', 'bicubic_clipped'}
- ▷ **Grayval** (output_control) grayval(-array) $\leadsto$ real / integer
Gray values of the selected image coordinates.

Result

If the parameters are valid, the operator `get_grayval_contour_xld` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`get_grayval_interpolated`

Module

Foundation

```
get_grayval_interpolated ( Image : : Row, Column,
                          Interpolation : Grayval )
```

Return gray values of an image at the positions given by tuples of rows and columns.

The operator `get_grayval_interpolated` returns interpolated gray values at several subpixel positions of an `Image`. The coordinates of the row positions are given in the tuple `Row`, the coordinates of column positions are given in the tuple `Column`. The gray values are returned in `Grayval` as a tuple of floating point numbers.

The interpolation method can be selected via the parameter `Interpolation`. The following interpolation methods are supported:

'bilinear': The parameter `Grayval` is computed using a bilinear interpolation of the four neighboring gray values of the selected coordinates. Note: direction and cyclic images are treated like byte images.

'bicubic': The parameter `Grayval` is computed using a bicubic interpolation of sixteen neighboring gray values of the selected coordinates. Direction and cyclic images are treated like byte images. In this mode, the resulting gray values may contain values that lie outside of the range of numbers that can be represented by the input image type.

'bicubic_clipped': The parameter `Grayval` is computed using a bicubic interpolation of sixteen neighboring gray values of the selected coordinates. Direction and cyclic images are treated like byte images. In this mode, resulting gray values that lie outside of the range of numbers that can be represented by the input image type are clipped to that range.

Note that `get_grayval_interpolated` does not take the domain of the image into account, i.e., if the domain has been reduced, e.g., with `reduce_domain`, gray values are returned even for points that lie outside the domain.

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex
Image whose gray values are to be accessed.
- ▷ **Row** (input_control) point.y(-array) $\leadsto$ real / integer
Row coordinates of positions.
Default: 0
Suggested values: Row $\in$ {0, 64, 128, 256, 512, 1024}
Value range: $-0.5 \leq \text{Row}$
Restriction: $-0.5 \leq \text{Row} \ \&\& \ \text{Row} < \text{height}(\text{Image}) - 0.5$
- ▷ **Column** (input_control) point.x(-array) $\leadsto$ real / integer
Column coordinates of positions.
Number of elements: Column == Row
Default: 0
Suggested values: Column $\in$ {0, 64, 128, 256, 512, 1024}
Value range: $-0.5 \leq \text{Column}$
Restriction: $-0.5 \leq \text{Column} \ \&\& \ \text{Column} < \text{width}(\text{Image}) - 0.5$
- ▷ **Interpolation** (input_control) string $\leadsto$ string
Interpolation method.
Default: 'bilinear'
List of values: Interpolation $\in$ {'bilinear', 'bicubic', 'bicubic_clipped'}
- ▷ **Grayval** (output_control) grayval(-array) $\leadsto$ real
Gray values of the selected image coordinates.

Result

If the parameters are valid, the operator `get_grayval_interpolated` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`read_image`

Alternatives

`get_grayval_contour_xld`, `get_grayval`

Module

Foundation

get_image_pointer1 (Image : : : Pointer, Type, Width, Height)
--

Access the pointer of a channel.

The operator `get_image_pointer1` returns a pointer to the first channel of the image `Image`. Additionally, the image type (`Type = 'byte', 'int2', 'uint2', etc.`) and the image size (width and height) are returned. Consequently, a direct access to the image data in the HALCON database via the pointer is possible from the programming language in which HALCON is used. An image is stored in HALCON linearized in row major order, i.e., line by line. Note that the image types 'complex' and 'vector_type' are handled in a specific way. In particular, 'complex' images are interleaved, i.e., the real and the imaginary parts are alternating. In contrast, 'vector_field' images consist of two matrices, one for the rows and one for the columns, which are stored in the HALCON database one after the other.

Attention

The pointer returned by `get_image_pointer1` may only be used as long as the corresponding image object exists in the HALCON database. This is the case as long as the corresponding variable in the programming language in which HALCON is used is valid. If this is not observed, unexpected behavior or program crashes may result.

If data is written to an existing image via the pointer, all image objects that reference the image are modified. If, for example, the domain of an image is restricted via `reduce_domain`, the original image object with the full domain and the image object with the reduced domain share the same image matrix (i.e., `get_image_pointer1` returns the same pointer for both images). Consequently, if one of the two images in this example is modified, both image objects are affected. Therefore, if the pointer is used to write image data in the programming language in which HALCON is used, the image data should be written into an image object that has been created solely for this purpose, e.g., using `gen_image1`. For multi-channel input images the type and the pointer of the first channel is returned.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image.
- ▷ **Pointer** (output_control) pointer(-array) $\leadsto$ *integer*
Pointer to the image data in the HALCON database.
- ▷ **Type** (output_control) string(-array) $\leadsto$ *string*
Type of image.
List of values: `Type` $\in$ { 'int1', 'int2', 'uint2', 'int4', 'int8', 'byte', 'real', 'direction', 'cyclic', 'complex', 'vector_field_absolute', 'vector_field_relative' }
- ▷ **Width** (output_control) extent.x(-array) $\leadsto$ *integer*
Width of image.
- ▷ **Height** (output_control) extent.y(-array) $\leadsto$ *integer*
Height of image.

Example

```
Hobject  Image;
char     typ[128];
Hlong    width,height;
unsigned char *ptr;

read_image(&Image,"fabrik");
get_image_pointer1(Image,(Hlong*)&ptr,typ,&width,&height);
```

Result

The operator `get_image_pointer1` returns the value 2 (`H_MSG_TRUE`) if exactly one image was passed. The behavior in case of empty input (no input images available) is set via the operator `set_system('no_object_result', <Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_image_pointer1_rect (Image : : : PixelPointer, Width, Height, VerticalPitch, HorizontalBitPitch, BitsPerPixel)

Access to the image data pointer and the image data inside the smallest rectangle of the domain of the input image.

The operator `get_image_pointer1_rect` returns the pointer `PixelPointer` which points to the beginning of the image data inside the smallest rectangle of the domain of `Image`. `VerticalPitch` corresponds to the width of the input image `Image` multiplied with the number of bytes per pixel (`HorizontalBitPitch` / 8). `Width` and `Height` correspond to the size of the smallest rectangle of the input region. `HorizontalBitPitch` is the horizontal distance (in bits) between two neighboring pixels. `BitsPerPixel` is the number of used bits per pixel. `get_image_pointer1_rect` is symmetrical to `gen_image1_rect`.

Attention

The operator `get_image_pointer1_rect` should only be used for entry into newly created images, since otherwise the gray values of other images might be overwritten (see relational structure).

Parameters

- ▷ **Image** (input_object)singlechannelimage $\rightsquigarrow$ object : byte / uint2 / int4
Input image (Himage).
- ▷ **PixelPointer** (output_control)pointer $\rightsquigarrow$ integer
Pointer to the image data.
- ▷ **Width** (output_control)extent.x $\rightsquigarrow$ integer
Width of the output image.
- ▷ **Height** (output_control)extent.y $\rightsquigarrow$ integer
Height of the output image.
- ▷ **VerticalPitch** (output_control)integer $\rightsquigarrow$ integer
Width(input image)*(HorizontalBitPitch/8).
- ▷ **HorizontalBitPitch** (output_control)integer $\rightsquigarrow$ integer
Distance between two neighboring pixels in bits .
- ▷ **BitsPerPixel** (output_control)integer $\rightsquigarrow$ integer
Number of used bits per pixel.

Example

```
Hobject      image,reg,imagereduced;
char         typ[128];
Hlong        width,height,vert_pitch,hori_bit_pitch,bits_per_pix, winID;
unsigned char *ptr;

open_window(0,0,512,512,"black",winID);
read_image(&image,"monkey");
draw_region(&reg,winID);
reduce_domain(image,reg,&imagereduced);
get_image_pointer1_rect(imagereduced,(Hlong*)&ptr,&width,&height,
                        &vert_pitch,&hori_bit_pitch,&bits_per_pix);
```

Result

The operator `get_image_pointer1_rect` returns the value 2 (`H_MSG_TRUE`) if exactly one image was passed. The behavior in case of empty input (no input images available) is set via the operator `set_system('no_object_result', <Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Foundation

```
get_image_pointer3 ( ImageRGB : : : PointerRed,  PointerGreen,
                    PointerBlue,  Type,  Width,  Height )
```

Access the pointers of a colored image.

The operator `get_image_pointer3` returns a C pointer to the three channels of a colored image (`ImageRGB`). Additionally the image type (`Type = 'byte', 'int2', 'float' etc.`) and the image size (`Width` and `Height`) are returned. Consequently a direct access to the image data in the HALCON database from the HALCON host language via the pointer is possible. An image is stored in HALCON as a vector of image lines. The image types 'complex' and 'vector_type' are handled in a specific way. In particular, 'complex' images are interleaved, i.e., the real and the imaginary parts are alternating, whereas 'vector_field' images consist of two matrices, one for the rows and one for the columns, which are stored in the HALCON database one after the other. The three channels must have the same pixel type and the same size.

Attention

Only one image can be passed. The operator `get_image_pointer3` should only be used for entry into newly created images, since otherwise the gray values of other images might be overwritten (see relational structure).

Parameters

- ▷ **ImageRGB** (input_object) multichannel-image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image.
- ▷ **PointerRed** (output_control) pointer(-array) $\leadsto$ *integer*
Pointer to the pixels of the first channel.
- ▷ **PointerGreen** (output_control) pointer(-array) $\leadsto$ *integer*
Pointer to the pixels of the second channel.
- ▷ **PointerBlue** (output_control) pointer(-array) $\leadsto$ *integer*
Pointer to the pixels of the third channel.
- ▷ **Type** (output_control) string(-array) $\leadsto$ *string*
Type of image.
List of values: `Type` $\in$ { 'int1', 'int2', 'uint2', 'int4', 'int8', 'byte', 'real', 'direction', 'cyclic', 'complex', 'vector_field_absolute', 'vector_field_relative' }
- ▷ **Width** (output_control) extent.x(-array) $\leadsto$ *integer*
Width of image.
- ▷ **Height** (output_control) extent.y(-array) $\leadsto$ *integer*
Height of image.

Result

The operator `get_image_pointer3` returns the value 2 (`H_MSG_TRUE`) if exactly one image is passed. The behavior in case of empty input (no input images available) is set via the operator `set_system('no_object_result', <Result>)`. If necessary an exception is raised.

Execution Information

get_image_size (Image : : : Width, Height)

Return the size of an image.

The operator `get_image_size` returns the image size (width and height) of the input image.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image.
- ▷ **Width** (output_control) extent.x(-array) $\leadsto$ *integer*
Width of image.
- ▷ **Height** (output_control) extent.y(-array) $\leadsto$ *integer*
Height of image.

Result

The operator `get_image_size` returns the value 2 (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system('no_object_result', <Result>)`. If necessary an exception is raised.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_image_time ( Image : : : MSecond, Second, Minute, Hour, Day,
                  YDay, Month, Year )
```

Request time at which the image was created.

The operator `get_image_time` returns the time at which the image was created internally in HALCON. This time doesn't necessarily correlate with the time the image was acquired.

For some image acquisition interfaces, the time of the acquisition can be queried with `get_framegrabber_param`.

Parameters

- ▷ **Image** (input_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image.
- ▷ **MSecond** (output_control) integer $\leadsto$ integer
Milliseconds (0..999).
- ▷ **Second** (output_control) integer $\leadsto$ integer
Seconds (0..59).
- ▷ **Minute** (output_control) integer $\leadsto$ integer
Minutes (0..59).
- ▷ **Hour** (output_control) integer $\leadsto$ integer
Hours (0..23).
- ▷ **Day** (output_control) integer $\leadsto$ integer
Day of the month (1..31).
- ▷ **YDay** (output_control) integer $\leadsto$ integer
Day of the year (1..366).
- ▷ **Month** (output_control) integer $\leadsto$ integer
Month (1..12).
- ▷ **Year** (output_control) integer $\leadsto$ integer
Year (xxxx).

Result

The operator `get_image_time` returns the value 2 (`H_MSG_TRUE`) if exactly one image was passed. The behavior in case of empty input (no input images available) is set via the operator `set_system('no_object_result', <Result>)`. If necessary an exception is raised.

```
get_image_type ( Image : : : Type )
```

Return the type of an image.

The operator `get_image_type` returns the image type (`Type` = 'byte', 'int2', 'uint2', etc.).

Attention

For multi-channel input images the type of the first channel is returned.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
- Input image.
- ▷ **Type** (output_control) string(-array) $\leadsto$ *string*
- Type of image.
- List of values:** Type $\in$ {'int1', 'int2', 'uint2', 'int4', 'int8', 'byte', 'real', 'direction', 'cyclic', 'complex', 'vector_field_absolute', 'vector_field_relative'}

Result

The operator `get_image_type` returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator `set_system('no_object_result', <Result>)`. If necessary an exception is raised.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`read_image`

15.2 Acquisition

close_framegrabber (: : AcqHandle :)

Close specified image acquisition device.

The operator `close_framegrabber` closes the image acquisition device specified by `AcqHandle`. In particular, allocated memory for data buffers is released and the image acquisition device is made available for other processes.

Attention

For a multithreaded application, `info_framegrabber`, `open_framegrabber`, and `close_framegrabber` are executed exclusively. Thus, they block the concurrent execution of each other, but run in parallel with all non-exclusive operators outside of this group.

Make sure that `close_framegrabber` is not called for a framegrabber handle that is being used by another thread concurrently.

Parameters

- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ *handle*
- Handle of the image acquisition device to be closed.

Result

If the specified image acquisition device could be closed, `close_framegrabber` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- AcqHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

grab_image , grab_image_async
<i>See also</i>
open_framegrabber
<i>Module</i>
Foundation

get_framegrabber_callback (: : AcqHandle, CallbackType : CallbackFunction, UserContext)

Query callback function of an image acquisition device.

The operator `get_framegrabber_callback` queries a callback function for the image acquisition device specified by `AcqHandle`. If the callback function was registered via `set_framegrabber_callback` before, `CallbackFunction` contains a pointer to it, otherwise NULL. Furthermore, `UserContext` contains a pointer to the user-specific context data that was set via `set_framegrabber_callback` (or NULL).

With the parameter `CallbackType`, you can select different callback types. Suggested values are:

- 'exception': The image acquisition has raised an exception.
- 'exposure_end': The exposure of the next image has been finished.
- 'exposure_start': The exposure of the next image has been started.
- 'transfer_end': A new image is ready to be fetched by `grab_image_async`.

Depending on the functionality of the underlying API, additional values for `CallbackType` are possible. All actually supported callback types of a specific image acquisition device can be queried by calling `get_framegrabber_param` with the parameter 'available_callback_types'. For more details see the documentation of the specific image acquisition interface.

<i>Attention</i>
For a multithreaded application, info_framegrabber , open_framegrabber , and close_framegrabber are executed exclusively.

`get_framegrabber_callback` runs in parallel with all non-exclusive operators inside and outside of this group.

<i>Parameters</i>
▷ AcqHandle (input_control) framegrabber $\leadsto$ handle Handle of the acquisition device to be used.
▷ CallbackType (input_control) string $\leadsto$ string Callback type. Default: 'transfer_end' Suggested values: CallbackType $\in$ {'exception', 'exposure_end', 'exposure_start', 'transfer_end'}
▷ CallbackFunction (output_control) pointer $\leadsto$ integer Pointer to the callback function.
▷ UserContext (output_control) pointer $\leadsto$ integer Pointer to user-specific context data.

Result

If the image acquisition device is open and the specified callback type is supported, the operator `get_framegrabber_callback` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_framegrabber_lut (: : AcqHandle : ImageRed, ImageGreen, ImageBlue)

Query look-up table of the image acquisition device.

The operator `get_framegrabber_lut` queries the look-up table (LUT) of the image acquisition device specified by `AcqHandle`. Note that this operation is not supported for all kinds of image acquisition devices.

Attention

For a multithreaded application, `info_framegrabber`, `open_framegrabber`, and `close_framegrabber` are executed exclusively.

`get_framegrabber_lut` runs in parallel with all non-exclusive operators inside and outside of this group.

Parameters

- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ *handle*
Handle of the acquisition device to be used.
- ▷ **ImageRed** (output_control) integer-array $\leadsto$ *integer*
Red level of the LUT entries.
- ▷ **ImageGreen** (output_control) integer-array $\leadsto$ *integer*
Green level of the LUT entries.
- ▷ **ImageBlue** (output_control) integer-array $\leadsto$ *integer*
Blue level of the LUT entries.

Result

The operator `get_framegrabber_lut` returns the value 2 (`H_MSG_TRUE`) if the image acquisition device is open.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_framegrabber`

get_framegrabber_param (: : AcqHandle, Param : Value)

Query specific parameters of an image acquisition device.

The operator `get_framegrabber_param` returns specific parameter values for the image acquisition device specified by [AcqHandle](#). The standard parameters listed below are available for all image acquisition devices. Additional parameters may be supported by a specific image acquisition device. A list of those parameters can be obtained with the query 'parameter' via [info_framegrabber](#).

Standard values for [Param](#), see [open_framegrabber](#):

'name' Name of the image acquisition interface.
 'horizontal_resolution' Horizontal resolution of the image acquisition device.
 'vertical_resolution' Vertical resolution of the image acquisition device.
 'image_width' Width of the specified image part.
 'image_height' Height of the specified image part.
 'start_row' Row coordinate of upper left corner of specified image part.
 'start_column' Column coordinate of upper left corner of specified image part.
 'field' Selected video field or full frame.
 'bits_per_channel' Number of transferred bits per pixel and image channel.
 'color_space' Color space of resulting image.
 'generic' Generic value with device-specific meaning.
 'external_trigger' External triggering ('true'/'false').
 'camera_type' Type of used camera (interface-specific).
 'device' Device name of the image acquisition device.
 'port' Port the image acquisition device is connected to.
 'line_in' Camera input line of multiplexer (optional).

Attention

For a multithreaded application, [info_framegrabber](#), [open_framegrabber](#), and [close_framegrabber](#) are executed exclusively.

`get_framegrabber_param` runs in parallel with all non-exclusive operators inside and outside of this group.

Parameters

- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ handle
Handle of the acquisition device to be used.
- ▷ **Param** (input_control) string(-array) $\leadsto$ string
Parameter of interest.
Default: 'revision'
Suggested values: `Param` $\in$ {'bits_per_channel', 'camera_type', 'color_space', 'continuous_grabbing', 'device', 'external_trigger', 'field', 'generic', 'grab_timeout', 'horizontal_resolution', 'image_available', 'image_height', 'image_width', 'line_in', 'name', 'port', 'revision', 'start_column', 'start_row', 'vertical_resolution', 'volatile'}
- ▷ **Value** (output_control) string(-array) $\leadsto$ string / real / integer / handle
Parameter value.

Result

If the image acquisition device is open and the specified parameter is supported, the operator `get_framegrabber_param` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

grab_data (: Image, Region, Contours : AcqHandle : Data)

Synchronous grab of images and preprocessed image data from the specified image acquisition device.

The operator `grab_data` grabs images and preprocessed image data via the image acquisition device specified by `AcqHandle`. The desired operational mode of the image acquisition device as well as a suitable image part and additional interface-specific settings can be specified using the operators `open_framegrabber` and `set_framegrabber_param`. Depending on the current configuration of the image acquisition device, the preprocessed image data can be returned in terms of images (`Image`), regions (`Region`), XLD contours (`Contours`), and control data (`Data`).

To abort the grab, the operator `set_framegrabber_param` with the parameter 'do_abort_grab' can be used if the specific image acquisition interface supports it. Note that as an exception from the description of the concurrent usage in multiple threads (see below) 'do_abort_grab' can also be used from another thread.

Attention

For a multithreaded application, `info_framegrabber`, `open_framegrabber`, and `close_framegrabber` are executed exclusively.

`grab_data` runs in parallel with all non-exclusive operators inside and outside of this group.

Parameters

- ▷ **Image** (output_object) image(-array) $\leadsto$ *object* : byte / real / uint2
Grabbed image data.
- ▷ **Region** (output_object) region(-array) $\leadsto$ *object*
Preprocessed image regions.
- ▷ **Contours** (output_object) xld_cont(-array) $\leadsto$ *object*
Preprocessed XLD contours.
- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ *handle*
Handle of the acquisition device to be used.
- ▷ **Data** (output_control) string(-array) $\leadsto$ *string* / real / integer / handle
Preprocessed control data.

Example

```
* Select a suitable image acquisition interface name AcqName
info_framegrabber(AcqName, 'port', Information, Values)
* Open image acquisition device using the default settings, see
* documentation of the actually used interface for more details
open_framegrabber(AcqName, 1, 1, 0, 0, 0, 0, 'default', -1, 'default', -1.0, \
                    'default', 'default', 'default', -1, -1, AcqHandle)
* Grab and segment image
grab_data (Image, Region, Contours, AcqHandle, Data)
* Process Region...
close_framegrabber(AcqHandle)
```

Result

If the image acquisition device is open and supports the image acquisition via `grab_data`, the operator `grab_data` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_framegrabber`, `grab_image_start`, `set_framegrabber_param`

Possible Successors

`grab_data_async`, `grab_image_start`, `grab_image`, `grab_image_async`, `set_framegrabber_param`, `close_framegrabber`

Module

Foundation

```
grab_data_async ( : Image, Region, Contours : AcqHandle,
                  MaxDelay : Data )
```

Asynchronous grab of images and preprocessed image data from the specified image acquisition device.

The operator `grab_data_async` requests asynchronously grabbed images and preprocessed image data from the image acquisition device specified by `AcqHandle`. By default, `grab_data_async` also starts the next asynchronous grab before the operator returns. More information about the behavior of a specific image acquisition device can be found in the corresponding interface documentation in the directory `doc/html/reference/acquisition`. The desired operational mode of the image acquisition device as well as a suitable image part and additional interface-specific settings can be specified using the operators `open_framegrabber` and `set_framegrabber_param`. Depending on the current configuration of the image acquisition device, the preprocessed image data can be returned in terms of images (`Image`), regions (`Region`), XLD contours (`Contours`), and control data (`Data`).

The grab of the next image is finished by calling `grab_data_async` or `grab_image_async`. If more than `MaxDelay` ms have passed since the asynchronous grab was started, the asynchronously grabbed image is considered as too old and a new image is grabbed, if necessary. If a negative value is assigned to `MaxDelay`, this control mechanism is deactivated.

To abort the grab, the operator `set_framegrabber_param` with the parameter 'do_abort_grab' can be used if the specific image acquisition interface supports it. Note that as an exception from the description of the concurrent usage in multiple threads (see below) 'do_abort_grab' can also be used from another thread.

Please note that if you call the operators `grab_image` or `grab_data` after `grab_data_async`, the asynchronous grab started by `grab_data_async` is aborted and a new synchronous grab is started.

Attention

For a multithreaded application, `info_framegrabber`, `open_framegrabber`, and `close_framegrabber` are executed exclusively.

`grab_data_async` runs in parallel with all non-exclusive operators inside and outside of this group.

Parameters

- ▷ **Image** (output_object) image(-array) $\leadsto$ object : byte / real / uint2
Grabbed image data.
- ▷ **Region** (output_object) region(-array) $\leadsto$ object
Pre-processed image regions.
- ▷ **Contours** (output_object) xld_cont(-array) $\leadsto$ object
Pre-processed XLD contours.

- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ *handle*
Handle of the acquisition device to be used.
- ▷ **MaxDelay** (input_control) number $\leadsto$ *real*
Maximum tolerated delay between the start of the asynchronous grab and the delivery of the image [ms].
Default: -1.0
Suggested values: MaxDelay $\in$ {-1.0, 20.0, 33.3, 40.0, 66.6, 80.0, 99.9}
- ▷ **Data** (output_control) string(-array) $\leadsto$ *string* / *real* / *integer* / *handle*
Pre-processed control data.

Example

```
* Select a suitable image acquisition interface name AcqName
open_framegrabber(AcqName,1,1,0,0,0,0,'default',-1,'default',-1.0, \
                  'default','default','default',-1,-1,AcqHandle)
* Grab image, segment it, and start next grab
grab_data_async (Image1, Region1, Contours1, AcqHandle, -1.0, Data1)
* Process data 1...
* Finish asynchronous grab, segment this image, and start next grab
grab_data_async (Image2, Region2, Contours2, AcqHandle, -1.0, Data2)
* Process data 2...
close_framegrabber(AcqHandle)
```

Result

If the image acquisition device is open and supports the image acquisition via `grab_data_async`, the operator `grab_data_async` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

grab_image (: Image : AcqHandle :)

Synchronous grab of an image from the specified image acquisition device.

The operator `grab_image` grabs an image via the image acquisition device specified by `AcqHandle`. The desired operational mode of the image acquisition device as well as a suitable image part and additional interface-specific settings can be specified using the operators `open_framegrabber` and `set_framegrabber_param`.

To abort the grab, the operator `set_framegrabber_param` with the parameter 'do_abort_grab' can be used if the specific image acquisition interface supports it. Note that as an exception from the description of the concurrent usage in multiple threads (see below) 'do_abort_grab' can also be used from another thread.

Attention

For a multithreaded application, `info_framegrabber`, `open_framegrabber`, and `close_framegrabber` are executed exclusively.

`grab_image` runs in parallel with all non-exclusive operators inside and outside of this group.

Parameters

- ▷ **Image** (output_object)image $\leadsto$ object : byte / uint2
Grabbed image.
- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ handle
Handle of the acquisition device to be used.

Example

```
* Select a suitable image acquisition interface name AcqName
info_framegrabber(AcqName, 'port', Information, Values)
* Open image acquisition device using the default settings, see
* documentation of the actually used interface for more details
open_framegrabber(AcqName, 1, 1, 0, 0, 0, 0, 'default', -1, 'default', -1.0, \
                  'default', 'default', 'default', -1, -1, AcqHandle)
grab_image(Image, AcqHandle)
close_framegrabber(AcqHandle)
```

Result

If the image could be acquired successfully, the operator `grab_image` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

grab_image_async (: Image : AcqHandle, MaxDelay :)

Asynchronous grab of an image from the specified image acquisition device.

The operator `grab_image_async` requests an asynchronously grabbed image from the image acquisition device specified by [AcqHandle](#). By default, `grab_image_async` also starts the next asynchronous grab before the operator returns. More information about the behavior of a specific image acquisition device can be found in the corresponding interface documentation in the directory `doc/html/reference/acquisition`. The desired operational mode of the image acquisition device as well as a suitable image part and additional interface-specific settings can be specified using the operators [open_framegrabber](#) and [set_framegrabber_param](#).

The grab is finished by calling `grab_image_async` or [grab_data_async](#). If more than [MaxDelay](#) ms have passed since the asynchronous grab was started, the asynchronously grabbed image is considered as too old and a new image is grabbed, if necessary. If a negative value is assigned to [MaxDelay](#), this control mechanism is deactivated.

To abort the grab, the operator [set_framegrabber_param](#) with the parameter 'do_abort_grab' can be used if the specific image acquisition interface supports it. Note that as an exception from the description of the concurrent usage in multiple threads (see below) 'do_abort_grab' can also be used from another thread.

Please note that if you call the operators [grab_image](#) or [grab_data](#) after `grab_image_async`, the asynchronous grab started by `grab_image_async` is aborted and a new synchronous grab is started.

Attention

For a multithreaded application, [info_framegrabber](#), [open_framegrabber](#), and [close_framegrabber](#) are executed exclusively.

`grab_image_async` runs in parallel with all non-exclusive operators inside and outside of this group.

Parameters

- ▷ **Image** (output_object)image $\leadsto$ object : byte / int2
Grabbed image.
- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ handle
Handle of the acquisition device to be used.
- ▷ **MaxDelay** (input_control) number $\leadsto$ real
Maximum tolerated delay between the start of the asynchronous grab and the delivery of the image [ms].
Default: -1.0
Suggested values: MaxDelay $\in$ {-1.0, 20.0, 33.3, 40.0, 66.6, 80.0, 99.9}

Example

```
* Select a suitable image acquisition interface named AcqName
open_framegrabber('AcqName', 1, 1, 0, 0, 0, 0, 'default', -1, \
                  'default', -1.0, 'default', 'default', 'default', -1, \
                  -1, AcqHandle)
* Grab image + start next grab
grab_image_async(Image1, AcqHandle, -1.0)
* Process Image1 ...
* Finish asynchronous grab + start next grab
grab_image_async(Image2, AcqHandle, -1.0)
* Process Image2 ...
close_framegrabber(AcqHandle)
```

Result

If the image acquisition device is open and supports asynchronous grabbing the operator `grab_image_async` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

grab_image_start (: : AcqHandle, MaxDelay :)

Start an asynchronous grab from the specified image acquisition device.

The operator `grab_image_start` starts the asynchronous grab of an image via the image acquisition device specified by [AcqHandle](#). The desired operational mode of the image acquisition device as well as a suitable image part and additional interface-specific settings can be specified using the operators [open_framegrabber](#) and [set_framegrabber_param](#).

The grab is finished via `grab_image_async` or `grab_data_async`. The `MaxDelay` parameter is obsolete and does not effect the new asynchronous grab. Note that you can check for a too old image by using the `MaxDelay` parameter of the operator `grab_image_async` or `grab_data_async`, respectively.

Please note that the operator `grab_image_start` makes sense only when used together with `grab_image_async` or `grab_data_async`. If you call the operators `grab_image` or `grab_data` instead, the asynchronous grab started by `grab_image_start` is aborted and a new synchronous grab is started.

To abort the grab, the operator `set_framegrabber_param` with the parameter 'do_abort_grab' can be used if the specific image acquisition interface supports it. Note that as an exception from the description of the concurrent usage in multiple threads (see below) 'do_abort_grab' can also be used from another thread.

Attention

For a multithreaded application, `info_framegrabber`, `open_framegrabber`, and `close_framegrabber` are executed exclusively.

`grab_image_start` runs in parallel with all non-exclusive operators inside and outside of this group.

Parameters

- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ handle
Handle of the acquisition device to be used.
- ▷ **MaxDelay** (input_control) number $\leadsto$ real
This parameter is obsolete and has no effect.
Default: -1.0
Suggested values: `MaxDelay` $\in$ {-1.0, 20.0, 33.3, 40.0, 66.6, 80.0, 99.9}

Example

```
* Select a suitable image acquisition interface named AcqName.
open_framegrabber('AcqName', 1, 1, 0, 0, 0, 0, 'default', -1, 'default', \
                  -1.0, 'default', 'default', 'default', -1, -1, AcqHandle)
* Start asynchronous grabbing.
grab_image_start(AcqHandle, -1)
* Run acquisition loop.
while (true)
    * Get image, start next grab.
    grab_image_async(Image, AcqHandle, -1.0)
    * Next: Do something with the grabbed image.
endwhile
close_framegrabber(AcqHandle)
```

Result

If the image acquisition device is open and supports asynchronous grabbing the operator `grab_image_start` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

info_framegrabber (: : Name, Query : Information, ValueList)

Query information about the specified image acquisition interface.

The operator `info_framegrabber` returns information about the image acquisition device `Name`. The desired information is specified via `Query`. A textual description according to the selected topic is returned in `Information`. If applicable, `ValueList` contains a list of supported values. Up to now, the following queries are possible:

- 'bits_per_channel': List of all supported values for the parameter `BitsPerChannel`, see [open_framegrabber](#).
- 'camera_type': Description and list of all supported values for the parameter `CameraType`, see [open_framegrabber](#).
- 'color_space': List of all supported values for the parameter `ColorSpace`, see [open_framegrabber](#).
- 'defaults': Interface-specific default values in `ValueList`, see [open_framegrabber](#).
- 'device': List of all supported values for the parameter `Device`, see [open_framegrabber](#).
- 'external_trigger': List of all supported values for the parameter `ExternalTrigger`, see [open_framegrabber](#).
- 'field': List of all supported values for the parameter `Field`, see [open_framegrabber](#).
- 'general': General information (in `Information`).
- 'generic': Generic value with device-specific meaning, see [open_framegrabber](#).
- 'horizontal_resolution': List of all supported values for the parameter `HorizontalResolution`, see [open_framegrabber](#).
- 'image_height': List of all supported values for the parameter `ImageHeight`, see [open_framegrabber](#).
- 'image_width': List of all supported values for the parameter `ImageWidth`, see [open_framegrabber](#).
- 'info_boards': Information about actually installed boards or cameras. This data is especially useful for the auto-detect mechanism of the Image Acquisition Assistant in HDevelop.
- 'line_in': List of all supported values for the parameter `LineIn`, see [open_framegrabber](#).
- 'parameters': List of all interface-specific parameters which are accessible via [set_framegrabber_param](#) or [get_framegrabber_param](#).
- 'parameters_readonly': List of all interface-specific parameters which are only accessible via [get_framegrabber_param](#).
- 'parameters_writeonly': List of all interface-specific parameters which are only accessible via [set_framegrabber_param](#).
- 'port': List of all supported values for the parameter `Port`, see [open_framegrabber](#).
- 'revision': Version number of the image acquisition interface.
- 'start_column': List of all supported values for the parameter `StartColumn`, see [open_framegrabber](#).
- 'start_row': List of all supported values for the parameter `StartRow`, see [open_framegrabber](#).
- 'vertical_resolution': List of all supported values for the parameter `VerticalResolution`, see [open_framegrabber](#).

Please check also the directory `doc/html/reference/acquisition` for documentation about specific image grabber interfaces.

Attention

For a multithreaded application, `info_framegrabber`, [open_framegrabber](#), and [close_framegrabber](#) are executed exclusively. Thus, they block the concurrent execution of each other, but run in parallel with all non-exclusive operators outside of this group.

On Windows Systems, error dialog boxes from the operating system can occur when dependency modules of the interface are not found, e.g., the according SDK was not installed. The occurrence of the error boxes can be controlled by setting Windows' Error Mode. Please refer to the description of `SetErrorMode` within the Windows MSDN documentation.

Parameters

- ▷ **Name** (input_control) string $\leadsto$ string
HALCON image acquisition interface name, i.e., name of the corresponding DLL (Windows) or shared library (Linux).
Default: 'File'
Suggested values: Name $\in$ {'ABS', 'ADLINK', 'AlkUSB3', 'Andor', 'BitFlow', 'Crevis', 'DahengCAM', 'DirectFile', 'DirectShow', 'Ensenso-NxLib', 'File', 'FocalSpecLCI', 'GenICamTL', 'GigEVision2', 'GingaDG', 'Ginga++', 'GStreamer', 'heliCamC3', 'KeyenceVJ', 'LinX', 'LPS36', 'LuCam', 'MatrixVisionAcquire', 'MediaFoundation', 'MILLite', 'MultiCam', 'O3D3xx', 'Opteon', 'PhoXi', 'PixeLINK', 'pylon', 'RealSense', 'SaperaLT', 'Sentech', 'SICK-3DCamera', 'SICK-ScanningRuler', 'SiliconSoftware', 'Slink', 'TWIN', 'uEye', 'USB3Vision', 'Video4Linux2', 'VRmUsbCam'}
- ▷ **Query** (input_control) string $\leadsto$ string
Name of the chosen query.
Default: 'info_boards'
List of values: Query $\in$ {'defaults', 'general', 'info_boards', 'parameters', 'parameters_readonly', 'parameters_writeonly', 'revision', 'bits_per_channel', 'camera_type', 'color_space', 'device', 'external_trigger', 'field', 'generic', 'horizontal_resolution', 'image_height', 'image_width', 'port', 'start_column', 'start_row', 'vertical_resolution'}
- ▷ **Information** (output_control) string $\leadsto$ string
Textual information (according to [Query](#)).
- ▷ **ValueList** (output_control) string-array $\leadsto$ string / integer / real
List of values (according to [Query](#)).

Example

```
* Select a suitable image acquisition interface name AcqName
info_framegrabber(AcqName, 'port', Information, Values)
* Open image acquisition device using the default settings, see
* documentation of the actually used interface for more details
open_framegrabber(AcqName, 1, 1, 0, 0, 0, 0, 'default', -1, 'default', -1.0, \
                  'default', 'default', 'default', -1, -1, AcqHandle)
grab_image(Image, AcqHandle)
close_framegrabber(AcqHandle)
```

Result

If the parameter values are correct and the specified image acquisition interface is available, `info_framegrabber` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[open_framegrabber](#)

Possible Successors

[open_framegrabber](#)

See also

[open_framegrabber](#)

Module

Foundation

```
open_framegrabber ( : : Name, HorizontalResolution,
                    VerticalResolution, ImageWidth, ImageHeight, StartRow,
                    StartColumn, Field, BitsPerChannel, ColorSpace, Generic,
                    ExternalTrigger, CameraType, Device, Port, LineIn : AcqHandle )
```

Open and configure an image acquisition device.

The operator `open_framegrabber` opens and configures the chosen image acquisition device. During this process, the connection to the image acquisition device is tested, the image acquisition device is locked for other processes, and, if necessary, memory is reserved for the data buffers. The actual image grabbing is done via the operators `grab_image`, `grab_data`, `grab_image_async`, or `grab_data_async`. If the image acquisition device is not needed anymore, it should be closed via the operator `close_framegrabber`, releasing it for other processes. Some image acquisition devices allow to open several instances of the same image acquisition device class.

For all parameters image acquisition device-specific default values can be chosen explicitly (see the parameter description below). Additional information for a specific image acquisition device is available via `info_framegrabber`. A comprehensive documentation of all image acquisition device-specific parameters can be found in the corresponding interface documentation in the directory `doc/html/reference/acquisition`.

The meaning of the particular parameters is as follows:

HorizontalResolution, VerticalResolution Desired resolution of the image acquisition device.

ImageWidth, ImageHeight Size of the image part to be returned by `grab_image` etc.

StartRow, StartColumn Upper left corner of the desired image area.

Field Desired half image ('first', 'second', or 'next') or selection of a full image.

BitsPerChannel Number of bits, which are transferred from the image acquisition device per pixel and image channel (typically 5, 8, 10, 12, or 16).

ColorSpace Output color format of the grabbed images (typically 'gray' or 'raw' for single-channel or 'rgb' or 'yuv' for three-channel images).

Generic Generic parameter with device-specific meaning which can be queried by `info_framegrabber`.

ExternalTrigger Activation of external triggering (if available).

CameraType More detailed specification of the desired image acquisition device (typically the type of the analog video format or the name of the desired camera configuration file).

Device Device name of the image acquisition device.

Port Port the image acquisition device is connected to.

LineIn Camera input line of multiplexer (if available).

The operator `open_framegrabber` returns a handle (`AcqHandle`) to the opened image acquisition device.

Attention

Due to the multitude of supported image acquisition devices, `open_framegrabber` contains a large number of parameters. However, not all parameters are needed for a specific image acquisition device.

For a multithreaded application, `info_framegrabber`, `open_framegrabber`, and `close_framegrabber` are executed exclusively. Thus, they block the concurrent execution of each other, but run in parallel with all non-exclusive operators outside of this group.

On Windows Systems, error dialog boxes from the operating system can occur when dependency modules of the interface are not found, e.g., the according SDK was not installed. The occurrence of the error boxes can be controlled by setting Windows' Error Mode. Please refer to the description of `SetErrorMode` within the Windows MSDN documentation.

Parameters

- ▷ **Name** (input_control) string $\leadsto$ string
HALCON image acquisition interface name, i.e., name of the corresponding DLL (Windows) or shared library (Linux).
- Default:** 'File'
- Suggested values:** Name $\in$ {'ABS', 'ADLINK', 'AlkUSB3', 'Andor', 'BitFlow', 'Crevis', 'DahengCAM', 'DirectFile', 'DirectShow', 'Ensenso-NxLib', 'File', 'FocalSpecLCI', 'GenICamTL', 'GigEVision2',

- 'GingaDG', 'Ginga++', 'GStreamer', 'heliCamC3', 'KeyenceVJ', 'LinX', 'LPS36', 'LuCam',
'MatrixVisionAcquire', 'MediaFoundation', 'MILLite', 'MultiCam', 'O3D3xx', 'Opteon', 'PhoXi',
'PixeLINK', 'pylon', 'RealSense', 'SaperaLT', 'Sentech', 'SICK-3DCamera', 'SICK-ScanningRuler',
'SiliconSoftware', 'Slink', 'TWIN', 'uEye', 'USB3Vision', 'Video4Linux2', 'VRmUsbCam']
- ▷ **HorizontalResolution** (input_control) extent.x $\leadsto$ integer
Desired horizontal resolution of image acquisition interface (absolute value or 1 for full resolution, 2 for half resolution, or 4 for quarter resolution).
Default: 1
Suggested values: HorizontalResolution $\in \{1, 2, 4, 1600, 1280, 768, 640, 384, 320, 192, 160, -1\}$
 - ▷ **VerticalResolution** (input_control) extent.y $\leadsto$ integer
Desired vertical resolution of image acquisition interface (absolute value or 1 for full resolution, 2 for half resolution, or 4 for quarter resolution).
Default: 1
Suggested values: VerticalResolution $\in \{1, 2, 4, 1200, 1024, 576, 480, 288, 240, 144, 120, -1\}$
 - ▷ **ImageWidth** (input_control) rectangle.extent.x $\leadsto$ integer
Width of desired image part (absolute value or 0 for HorizontalResolution - 2*StartColumn).
Default: 0
Suggested values: ImageWidth $\in \{0, -1\}$
 - ▷ **ImageHeight** (input_control) rectangle.extent.y $\leadsto$ integer
Height of desired image part (absolute value or 0 for VerticalResolution - 2*StartRow).
Default: 0
Suggested values: ImageHeight $\in \{0, -1\}$
 - ▷ **StartRow** (input_control) rectangle.origin.y $\leadsto$ integer
Line number of upper left corner of desired image part (or border height if ImageHeight = 0).
Default: 0
Suggested values: StartRow $\in \{0, -1\}$
 - ▷ **StartColumn** (input_control) rectangle.origin.x $\leadsto$ integer
Column number of upper left corner of desired image part (or border width if ImageWidth = 0).
Default: 0
Suggested values: StartColumn $\in \{0, -1\}$
 - ▷ **Field** (input_control) string $\leadsto$ string
Desired half image or full image.
Default: 'default'
Suggested values: Field $\in \{'first', 'second', 'next', 'interlaced', 'progressive', 'default'\}$
 - ▷ **BitsPerChannel** (input_control) integer(-array) $\leadsto$ integer
Number of transferred bits per pixel and image channel (-1: device-specific default value).
Default: -1
Suggested values: BitsPerChannel $\in \{5, 8, 10, 12, 14, 16, -1\}$
 - ▷ **ColorSpace** (input_control) string(-array) $\leadsto$ string
Output color format of the grabbed images, typically 'gray' or 'raw' for single-channel or 'rgb' or 'yuv' for three-channel images ('default': device-specific default value).
Default: 'default'
Suggested values: ColorSpace $\in \{'gray', 'raw', 'rgb', 'yuv', 'default'\}$
 - ▷ **Generic** (input_control) string(-array) $\leadsto$ real / string / integer
Generic parameter with device-specific meaning.
Default: -1
 - ▷ **ExternalTrigger** (input_control) string $\leadsto$ string
External triggering.
Default: 'default'
List of values: ExternalTrigger $\in \{'true', 'false', 'default'\}$
 - ▷ **CameraType** (input_control) string(-array) $\leadsto$ string
Type of used camera ('default': device-specific default value).
Default: 'default'
Suggested values: CameraType $\in \{'ntsc', 'pal', 'auto', 'default'\}$
 - ▷ **Device** (input_control) string(-array) $\leadsto$ string
Device the image acquisition device is connected to ('default': device-specific default value).
Default: 'default'
Suggested values: Device $\in \{'-1', '0', '1', '2', '3', 'default'\}$

- ▷ **Port** (input_control) integer(-array) $\leadsto$ integer
Port the image acquisition device is connected to (-I: device-specific default value).
Default: -1
Suggested values: Port $\in \{0, 1, 2, 3, -1\}$
- ▷ **LineIn** (input_control) integer(-array) $\leadsto$ integer
Camera input line of multiplexer (-I: device-specific default value).
Default: -1
Suggested values: LineIn $\in \{1, 2, 3, 4, -1\}$
- ▷ **AcqHandle** (output_control) framegrabber $\leadsto$ handle
Handle of the opened image acquisition device.

Example

```
* Select a suitable image acquisition interface name AcqName
info_framegrabber(AcqName, 'port', Information, Values)
* Open image acquisition device using the default settings, see
* documentation of the actually used interface for more details
open_framegrabber(AcqName, 1, 1, 0, 0, 0, 0, 'default', -1, 'default', -1.0, \
                  'default', 'default', 'default', -1, -1, AcqHandle)
grab_image(Image, AcqHandle)
close_framegrabber(AcqHandle)
```

Result

If the parameter values are correct and the desired image acquisition device could be opened, `open_framegrabber` returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

[info_framegrabber](#)

Possible Successors

[grab_image](#), [grab_data](#), [grab_image_start](#), [grab_image_async](#), [grab_data_async](#),
[set_framegrabber_param](#), [set_framegrabber_callback](#)

See also

[info_framegrabber](#), [close_framegrabber](#), [grab_image](#)

Module

Foundation

```
set_framegrabber_callback ( : : AcqHandle, CallbackType,
                             CallbackFunction, UserContext : )
```

Register a callback function for an image acquisition device.

The operator `set_framegrabber_callback` registers a callback function for the image acquisition device specified by `AcqHandle`. The parameter `CallbackFunction` contains a pointer to the function to register, while `CallbackType` specifies to which function of the underlying API the callback should be connected.

Suggested values for `CallbackType` are:

'exception': The image acquisition has raised an exception.

'exposure_end': The exposure of the next image has been finished.

'exposure_start': The exposure of the next image has been started.

'transfer_end': A new image is ready to be fetched by `grab_image_async`.

Depending on the functionality of the underlying API, additional values for `CallbackType` are possible. All actually supported callback types of a specific image acquisition device can be queried by calling `get_framegrabber_param` with the parameter `'available_callback_types'`. For more details see the documentation of the specific image acquisition interface.

Once the callback is registered, on every occurrence of the underlying event (e.g., the notification that the exposure has finished) the specified callback function `CallbackFunction` will be called. If `CallbackFunction` is set to NULL, the corresponding callback will be unregistered.

The signature of the callback function is the following:

```
HRESULT HAcqCallback(void *AcqHandle, void *Context, void *UserContext)
```

The first parameter of the callback function contains the handle to the image acquisition device passed in `AcqHandle`, the second one provides a pointer to interface-specific context data, and the third parameter is a user-specific pointer that is specified in `UserContext`.

Attention

For a multithreaded application, `info_framegrabber`, `open_framegrabber`, and `close_framegrabber` are executed exclusively.

`set_framegrabber_callback` runs in parallel with all non-exclusive operators inside and outside of this group.

Parameters

- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ *handle*
Handle of the acquisition device to be used.
- ▷ **CallbackType** (input_control) string $\leadsto$ *string*
Callback type.
Default: `'transfer_end'`
Suggested values: `CallbackType` $\in$ `{'exception', 'exposure_end', 'exposure_start', 'transfer_end'}`
- ▷ **CallbackFunction** (input_control) pointer $\leadsto$ *integer*
Pointer to the callback function to be set.
- ▷ **UserContext** (input_control) pointer $\leadsto$ *integer*
Pointer to user-specific context data.

Result

If the image acquisition device is open and the specified callback was registered successfully, the operator `set_framegrabber_callback` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `AcqHandle`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`open_framegrabber`, `set_framegrabber_param`

Possible Successors

`grab_image`, `grab_data`, `grab_image_start`, `grab_image_async`, `grab_data_async`,
`get_framegrabber_param`

Module

Foundation

```
set_framegrabber_lut ( : : AcqHandle, ImageRed, ImageGreen,
                        ImageBlue : )
```

Set look-up table of the image acquisition device.

The operator `set_framegrabber_lut` sets the look-up table (LUT) of the image acquisition device specified by [AcqHandle](#). Note that this operation is not supported for all kinds of image acquisition devices.

Attention

For a multithreaded application, [info_framegrabber](#), [open_framegrabber](#), and [close_framegrabber](#) are executed exclusively.

`set_framegrabber_lut` runs in parallel with all non-exclusive operators inside and outside of this group.

Parameters

- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ *handle*
Handle of the acquisition device to be used.
- ▷ **ImageRed** (input_control) integer-array $\leadsto$ *integer*
Red level of the LUT entries.
- ▷ **ImageGreen** (input_control) integer-array $\leadsto$ *integer*
Green level of the LUT entries.
- ▷ **ImageBlue** (input_control) integer-array $\leadsto$ *integer*
Blue level of the LUT entries.

Result

The operator `set_framegrabber_lut` returns the value 2 (H_MSG_TRUE) if the specified LUT is correct and the image acquisition device is open.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `AcqHandle`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

```
set_framegrabber_param ( : : AcqHandle, Param, Value : )
```

Set specific parameters of an image acquisition device.

The operator `set_framegrabber_param` sets specific parameters for the image acquisition device specified by [AcqHandle](#). Additional information for a specific image acquisition device is available via [info_framegrabber](#). A comprehensive documentation of all image acquisition device-specific parameters can be found in the corresponding interface documentation in the directory `doc/html/reference/acquisition`.

Attention

For a multithreaded application, [info_framegrabber](#), [open_framegrabber](#), and [close_framegrabber](#) are executed exclusively.

[set_framegrabber_param](#) runs in parallel with all non-exclusive operators inside and outside of this group.

Parameters

- ▷ **AcqHandle** (input_control) framegrabber $\leadsto$ *handle*
Handle of the acquisition device to be used.
- ▷ **Param** (input_control) string(-array) $\leadsto$ *string*
Parameter name.
Suggested values: Param $\in$ {'color_space', 'continuous_grabbing', 'external_trigger', 'grab_timeout', 'image_height', 'image_width', 'port', 'start_column', 'start_row', 'volatile'}
- ▷ **Value** (input_control) string(-array) $\leadsto$ *string* / real / integer / handle
Parameter value to be set.

Result

If the image acquisition device is open and the specified parameter / parameter value is supported, the operator [set_framegrabber_param](#) returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- AcqHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

15.3 Channel

access_channel (MultiChannelImage : Image : Channel :)

Access a channel of a multi-channel image.

The operator [access_channel](#) accesses a channel of the (multi-channel) input image. The result is a one-channel image. The definition domain of the input is adopted. The channels are numbered from 1 to n. The number of channels can be determined via the operator [count_channels](#).

Parameters

- ▷ **MultiChannelImage** (input_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic /
int1 / int2 / uint2 / int4 / int8 / real /
complex / vector_field

Multi-channel image.

- ▷ **Image** (output_object) singlechannelimage $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

One channel of MultiChannelImage.

- ▷ **Channel** (input_control) channel $\leadsto$ *integer*
Index of channel to be accessed.

Default: 1

Suggested values: Channel $\in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12\}$

Value range: $1 \leq \text{Channel}$

Example

```
read_image(&Color, "patras");    /* read color image */
access_channel(Color, &Red, 1); /* extract red channel */
disp_image(Red, WindowHandle);
```

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

append_channel (MultiChannelImage, Image : ImageExtended : :)
--

Append additional matrices (channels) to the image.

The operator `append_channel` appends the matrices of the image `Image` to the matrices of `MultiChannelImage`. The result is an image containing as many matrices (channels) as `MultiChannelImage` and `Image` combined. The definition domain of the output image is calculated as the intersection of the definition domains of both input images. `MultiChannelImage` may be a region only that is then interpreted as the definition domain of an image without channels. No new storage is allocated for the multi-channel image. Instead, the created multi-channel image contains references to the existing input images.

Parameters

- ▷ **MultiChannelImage** (input_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Multi-channel image.

- ▷ **Image** (input_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Image to be appended.

- ▷ **ImageExtended** (output_object) multichannel-image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Image appended by `Image`.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

channels_to_image (Images : MultiChannelImage : :)

Convert one-channel images into a multi-channel image

The operator `channels_to_image` converts several one-channel images into a multi-channel image. The new definition domain is the intersection of the definition domains of the input images. No new storage is allocated for the multi-channel images, unless images of different dimensions are combined. In that case, new storage is allocated for all images that do not have both maximum width and height among all input images. For all images with maximum dimensions, the created multi-channel image contains references to the existing input images.

Parameters

- ▷ **Images** (input_object) singlechannelimage-array $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
- One-channel images to be combined into a one-channel image.
- ▷ **MultiChannelImage** (output_object) multichannel-image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Multi-channel image.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

Module

Foundation

compose2 (Image1, Image2 : MultiChannelImage : :)

Convert two images into a two-channel image.

The operator `compose2` converts 2 one-channel images into a 2-channel image. The definition domain is calculated as the intersection of the definition domains of the input images. No new storage is allocated for the multi-channel image. Instead, the created multi-channel image contains references to the existing input images.

Parameters

- ▷ **Image1** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image 1.
- ▷ **Image2** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image 2.
- ▷ **MultiChannelImage** (output_object) multichannel-image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Multi-channel image.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

compose3 (Image1, Image2, Image3 : MultiChannelImage : :)
--

Convert 3 images into a three-channel image.

The operator `compose3` converts 3 one-channel images into a 3-channel image. The definition domain is calculated as the intersection of the definition domains of the input images. No new storage is allocated for the multi-channel image. Instead, the created multi-channel image contains references to the existing input images.

Parameters

- ▷ **Image1** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image 1.
- ▷ **Image2** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image 2.
- ▷ **Image3** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image 3.
- ▷ **MultiChannelImage** (output_object) multichannel-image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Multi-channel image.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

```
compose4 ( Image1, Image2, Image3,
           Image4 : MultiChannelImage : : )
```

Convert 4 images into a four-channel image.

The operator `compose4` converts 4 one-channel images into a 4-channel image. The definition domain is calculated as the intersection of the definition domains of the input images. No new storage is allocated for the multi-channel image. Instead, the created multi-channel image contains references to the existing input images.

Parameters

- ▷ **Image1** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
 Input image 1.
- ▷ **Image2** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
 Input image 2.
- ▷ **Image3** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
 Input image 3.
- ▷ **Image4** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
 Input image 4.
- ▷ **MultiChannelImage** (output_object) multichannel-image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
 Multi-channel image.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

Module

Foundation

```
compose5 ( Image1, Image2, Image3, Image4,
           Image5 : MultiChannelImage : : )
```

Convert 5 images into a five-channel image.

The operator `compose5` converts 5 one-channel images into a 5-channel image. The definition domain is calculated as the intersection of the definition domains of the input images. No new storage is allocated for the multi-channel image. Instead, the created multi-channel image contains references to the existing input images.

Parameters

- ▷ **Image1** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image 1.
- ▷ **Image2** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image 2.
- ▷ **Image3** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image 3.

count_channels (MultiChannelImage : : : Channels)
--

Count channels of image.

The operator `count_channels` counts the number of channels of all input images.

Parameters

- ▷ **MultiChannelImage** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
One- or multi-channel image.

- ▷ **Channels** (output_control) integer(-array) $\leadsto$ integer
Number of channels.

Example

```
read_image (&Color, "patras");
count_channels (Color, &num_channels);
for (i=1; i<=num_channels; i++)
{
    access_channel (Color, &Channel, i);
    disp_image (Channel, WindowHandle);
    clear_obj (Channel);
}
```

Execution Information

image_to_channels (MultiChannelImage : Images : :)

Convert a multi-channel image into One-channel images

The operator `image_to_channels` generates a one-channel image for each channel of the multi-channel image in `MultiChannelImage`. The definition domains are adopted from the input image. As many images are created as `MultiChannelImage` has channels. No new storage is allocated for the output images. Instead, the created images contain references to the existing input image channels.

Parameters

▷ **MultiChannelImage** (input_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Multi-channel image to be decomposed.

▷ **Images** (output_object) singlechannelimage-array $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Generated one-channel images.

Execution Information

- Supports objects on compute devices.

15.4 Creation

copy_image (Image : DupImage : :)
--

Copy an image and allocate new memory for it.

`copy_image` copies the input image into a new image with the same domain as the input image. In contrast to HALCON operators such as `copy_obj`, physical copies of all channels are created. This can be used, for example, to modify the gray values of the new image (see [get_image_pointer1](#)).

Parameters

▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Image to be copied.

▷ **DupImage** (output_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Copied image.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

[get_image_pointer1](#)

Module

Foundation

gen_image1 (: Image : Type, Width, Height, PixelPointer :)

Create an image from a pointer to the pixels.

The operator `gen_image1` creates an image of the size `Width × Height`. The pixels in `PixelPointer` are stored line-sequentially. The type of the given pixels (`PixelPointer`) must correspond to `Type` (see [gen_image_const](#) for a more detailed description of the pixel types). The storage for the new image is newly created by HALCON. Thus, the storage on the `PixelPointer` can be released after the call. Note that how to pass a pointer value depends on the used operator signature and programming environment. Make sure to pass the actual memory address where the image data is stored, not the address of a pointer variable. Care must be taken not to truncate 64-bit pointers on 64-bit architectures.

Attention

`gen_image1` does not check whether the `PixelPointer` is valid or not. Thus, it must be ensured by the user that it is valid. Otherwise, the program may crash!

Parameters

- ▷ **Image** (output_object) image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Created image with new image matrix.
- ▷ **Type** (input_control) string $\leadsto$ string
Pixel type.
Default: 'byte'
List of values: Type $\in$ {'byte', 'direction', 'cyclic', 'int1', 'int2', 'uint2', 'int4', 'real'}
- ▷ **Width** (input_control) extent.x $\leadsto$ integer
Width of image.
Default: 512
Suggested values: Width $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Width (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Height** (input_control) extent.y $\leadsto$ integer
Height of image.
Default: 512
Suggested values: Height $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Height (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **PixelPointer** (input_control) pointer $\leadsto$ integer
Pointer to first gray value.

Example

```

void NewImage(Hobject *new)
{
    unsigned char  image[768*525];
    int            r,c;
    for (r=0; r<525; r++)
        for (c=0; c<768; c++)
            image[r*768+c] = c % 255;
    gen_image1(new, "byte", 768, 525, (Hlong) image);
}

```

Result

If the parameter values are correct, the operator `gen_image1` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Alternatives

[gen_image3](#), [gen_image1_extern](#), [gen_image_const](#), [get_image_pointer1](#)

See also

[reduce_domain](#), [paint_gray](#), [paint_region](#), [set_grayval](#)

Module

Foundation

gen_image1_extern (: Image : Type, Width, Height, PixelPointer, ClearProc :)

Create an image from a pointer on the pixels with storage management.

The operator `gen_image1_extern` creates an image of the size `Width × Height`. The pixels in `PixelPointer` are stored line-sequentially. The type of the given pixels (`PixelPointer`) must correspond to `Type` (see [gen_image_const](#) for a more detailed description of the image types). Note that how to pass a pointer value depends on the used operator signature and programming environment. Make sure to pass the actual memory address where the image data is stored, not the address of a pointer variable. Care must be taken not to truncate 64-bit pointers on 64-bit architectures.

The memory for the new image is not newly allocated by HALCON, contrary to [gen_image1](#), and thus is not copied either. This means that the memory space that `PixelPointer` points to must be released by deleting the object `Image`. This is done by the procedure `ClearProc` provided by the caller. This procedure must have the following signature

```
void ClearProc(void* ptr);
```

and will be called using `__cdecl` calling convention when deleting `Image`. If the memory shall not be released (in the case of frame grabbers or static memory) a procedure “without trunk” or the NULL-Pointer can be passed. Analogous to the parameter `PixelPointer` the pointer has to be passed to the procedure depending on the used operator signature and programming environment.

Attention

`gen_image1_extern` does not check if enough memory for an image of `Width × Height` is allocated in `PixelPointer`.

Also, `gen_image1_extern` does not check whether the `PixelPointer` is valid or not. Thus, it must be ensured by the user that it is valid. Otherwise, the program may crash!

Parameters

- ▷ **Image** (output_object) image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Created HALCON image.
- ▷ **Type** (input_control) string $\leadsto$ string
Pixel type.
Default: 'byte'
List of values: Type $\in$ {'int1', 'int2', 'uint2', 'int4', 'byte', 'real', 'direction', 'cyclic'}
- ▷ **Width** (input_control) extent.x $\leadsto$ integer
Width of image.
Default: 512
Suggested values: Width $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Width (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Height** (input_control) extent.y $\leadsto$ integer
Height of image.
Default: 512
Suggested values: Height $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Height (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **PixelPointer** (input_control) pointer $\leadsto$ integer
Pointer to the first gray value.
- ▷ **ClearProc** (input_control) pointer $\leadsto$ integer
Pointer to the procedure re-releasing the memory of the image when deleting the object.
Default: 0

Example

```
void NewImage(Hobject *new)
{
    unsigned char *image;
    int r, c;
    image = malloc(640*480);
    for (r=0; r<480; r++)
        for (c=0; c<640; c++)
            image[r*640+c] = c % 255;
    gen_image1_extern(new, "byte", 640, 480, (Hlong) image, (Hlong) free);
}
```

Result

The operator `gen_image1_extern` returns the value 2 (`H_MSG_TRUE`) if the parameter values are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

[reduce_domain](#), [paint_gray](#), [paint_region](#), [set_grayval](#)

Module

Foundation

```

gen_image1_rect ( : Image : PixelPointer, Width, Height,
                  VerticalPitch, HorizontalBitPitch, BitsPerPixel, DoCopy,
                  ClearProc : )

```

Create an image with a rectangular domain from a pointer on the pixels (with storage management).

The operator `gen_image1_rect` creates an image of size $(\text{VerticalPitch} / (\text{HorizontalBitPitch} / 8)) * \text{Height}$. The pixels pointed to by `PixelPointer` are stored line by line. Note that how to pass a pointer value depends on the used operator signature and programming environment. Make sure to pass the actual memory address where the image data is stored, not the address of a pointer variable. Care must be taken not to truncate 64-bit pointers on 64-bit architectures.

`VerticalPitch` determines the distance (in bytes) between pixel m in row n and pixel m in row $n+1$ inside of memory. All rows of the 'input image' have the same vertical pitch. The width of the output image is $\text{VerticalPitch} / (\text{HorizontalBitPitch} / 8)$, its height is `Height`. The domain of the output image `Image` is a rectangle of the size $\text{Width} * \text{Height}$. The parameter `HorizontalBitPitch` is the horizontal distance (in bits) between two neighboring pixels. `BitsPerPixel` is the number of used bits per pixel.

If `DoCopy` is set '`true`', the image data pointed to by `PixelPointer` is copied and memory for the new image is newly allocated by HALCON. Else the image data is not duplicated and the memory space that `PixelPointer` points to must be released when deleting the object `Image`. This is done by the procedure `ClearProc` provided by the caller. This procedure must have the following signature

```
void ClearProc(void* ptr);
```

and will be called using `__cdecl` calling convention when deleting `Image`. If the memory shall not be released (in the case of frame grabbers or static memory) a procedure "without trunk" or the NULL-pointer can be passed. Analogously to the parameter `PixelPointer` the pointer has to be passed to the procedure depending on the used operator signature and programming environment. If `DoCopy` is '`true`' then `ClearProc` is irrelevant. The operator `gen_image1_rect` is symmetrical to `get_image_pointer1_rect`.

Attention

`gen_image1_rect` does not check whether the `PixelPointer` is valid or not. Thus, it must be ensured by the user that it is valid. Otherwise, the program may crash!

Parameters

- ▷ **Image** (output_object) image $\leadsto$ object : byte / uint2 / int4
Created HALCON image.
- ▷ **PixelPointer** (input_control) pointer $\leadsto$ integer
Pointer to the first pixel.
- ▷ **Width** (input_control) extent.x $\leadsto$ integer
Width of the image.
Default: 512
Suggested values: $\text{Width} \in \{128, 256, 512, 1024\}$
Value range: $1 \leq \text{Width} \text{ (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Height** (input_control) extent.y $\leadsto$ integer
Height of the image.
Default: 512
Suggested values: $\text{Height} \in \{128, 256, 512, 1024\}$
Value range: $1 \leq \text{Height} \text{ (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **VerticalPitch** (input_control) integer $\leadsto$ integer
Distance (in bytes) between pixel m in row n and pixel m in row $n+1$ of the 'input image'.
Restriction: $\text{VerticalPitch} \geq \text{Width} * \text{HorizontalBitPitch} / 8$
- ▷ **HorizontalBitPitch** (input_control) integer $\leadsto$ integer
Distance between two neighboring pixels in bits.
Default: 8
List of values: $\text{HorizontalBitPitch} \in \{8, 16, 32\}$

- ▷ **BitsPerPixel** (input_control) integer $\leadsto$ integer
 Number of used bits per pixel.
Default: 8
List of values: BitsPerPixel $\in$ {8, 9, 10, 11, 12, 13, 14, 15, 16, 32}
Restriction: BitsPerPixel $\leq$ HorizontalBitPitch
- ▷ **DoCopy** (input_control) string $\leadsto$ string
 Copy image data.
Default: 'false'
Suggested values: DoCopy $\in$ {'true', 'false'}
- ▷ **ClearProc** (input_control) pointer $\leadsto$ integer
 Pointer to the procedure releasing the memory of the image when deleting the object.
Default: 0

Example

```
void NewImage (Hobject *new)
{
    unsigned char    *image;
    int              r, c;

    image = malloc(640*480);
    for (r=0; r<480; r++)
        for (c=0; c<640; c++)
            image[r*640+c] = c % 255;
    gen_image1_rect (new, (Hlong)image, 400, 480, 640, 8, 8, 'false', (long)free);
}
```

Result

The operator `gen_image1_rect` returns the value 2 (`H_MSG_TRUE`) if the parameter values are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

Module

Foundation

```
gen_image3 ( : ImageRGB : Type, Width, Height, PixelPointerRed,
              PixelPointerGreen, PixelPointerBlue : )
```

Create an image from three pointers to the pixels (red/green/blue).

The operator `gen_image3` creates a three-channel image of the size `Width` $\times$ `Height`. The pixels in `PixelPointerRed`, `PixelPointerGreen` and `PixelPointerBlue` are stored line-sequentially. The type of the given pixels (`PixelPointerRed` etc.) must correspond to `Type` (see [gen_image_const](#) for a more detailed description of the pixel types). The storage for the new image is newly created by HALCON. Thus, it can be released after the call. Note that how to pass a pointer value depends on the used operator signature and

programming environment. Make sure to pass the actual memory address where the image data is stored, not the address of a pointer variable. Care must be taken not to truncate 64-bit pointers on 64-bit architectures.

Attention

`gen_image3` does not check whether the pixels in `PixelPointerRed`, `PixelPointerGreen`, and `PixelPointerBlue` are valid or not. Thus, it must be ensured by the user that they are valid. Otherwise, the program may crash!

Parameters

- ▷ **ImageRGB** (output_object) image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Created image with new image matrix.
- ▷ **Type** (input_control) string $\leadsto$ string
Pixel type.
Default: 'byte'
List of values: Type $\in$ {'byte', 'direction', 'cyclic', 'int1', 'int2', 'uint2', 'int4', 'real'}
- ▷ **Width** (input_control) extent.x $\leadsto$ integer
Width of image.
Default: 512
Suggested values: Width $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Width (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Height** (input_control) extent.y $\leadsto$ integer
Height of image.
Default: 512
Suggested values: Height $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Height (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **PixelPointerRed** (input_control) pointer $\leadsto$ integer
Pointer to first red value (channel 1).
- ▷ **PixelPointerGreen** (input_control) pointer $\leadsto$ integer
Pointer to first green value (channel 2).
- ▷ **PixelPointerBlue** (input_control) pointer $\leadsto$ integer
Pointer to first blue value (channel 3).

Example

```
void NewRGBImage (Hobject *new)
{
    unsigned char  red[768*525];
    unsigned char  green[768*525];
    unsigned char  blue[768*525];
    int            r,c;
    for (r=0; r<525; r++)
        for (c=0; c<768; c++)
        {
            red[r*768+c]    = c % 255;
            green[r*768+c]  = (767 - c) % 255;
            blue[r*768+c]   = r % 255;
        }
    gen_image3 (new, "byte", 768, 525, (Hlong) red, (long) green, (long) blue);
}

main()
{
    Hobject  rgb;
    open_window(0, 0, 768, 525, 0, "", "", &WindowHandle);
    NewRGBImage (&rgb);
}
```

```
disp_color(rgb, WindowHandle);
}
```

Result

If the parameter values are correct, the operator `gen_image3` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Module

Foundation

gen_image3_extern (: Image : Type, Width, Height, PointerRed, PointerGreen, PointerBlue, ClearProc :)

Create a three-channel image from three pointers on the pixels with storage management.

The operator `gen_image3_extern` creates a three-channel image of the size `Width` × `Height`. The pixels in `PointerRed`, `PointerGreen`, and `PointerBlue` are stored line-sequentially. The type of the given pixels must correspond to `Type` (see `gen_image_const` for a more detailed description of the image types). Note that how to pass a pointer value depends on the used operator signature and programming environment. Make sure to pass the actual memory address where the image data is stored, not the address of a pointer variable. Care must be taken not to truncate 64-bit pointers on 64-bit architectures.

The memory for the new image is not newly allocated by HALCON, contrary to `gen_image3`, and thus is not copied either. This means that the memory space that `PointerRed`, `PointerGreen`, and `PointerBlue` point to must be released by deleting the object `Image`. This is done by the procedure `ClearProc` provided by the caller. This procedure must have the following signature

```
void ClearProc(void* ptr);
```

and will be called using `__cdecl` calling convention when deleting `Image`. If the memory shall not be released (in the case of frame grabbers or static memory) a procedure “without trunk” or the NULL-Pointer can be passed. Analogous to the parameters `PointerRed`, `PointerGreen`, and `PointerBlue` the pointer has to be passed to the procedure depending on the used operator signature and programming environment.

Attention

`gen_image3_extern` does not check if enough memory for an image of `Width` × `Height` is allocated in `PointerRed`, `PointerGreen`, and `PointerBlue`.

Also, `gen_image3_extern` does not check whether the pixels in `PointerRed`, `PointerGreen`, and `PointerBlue` are valid or not. Thus, it must be ensured by the user that they are valid. Otherwise, the program may crash!

Parameters

- ▷ **Image** (output_object) image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Created HALCON image.
- ▷ **Type** (input_control) string $\leadsto$ string
Pixel type.
Default: 'byte'
List of values: Type $\in$ {'int1', 'int2', 'uint2', 'int4', 'byte', 'real', 'direction', 'cyclic'}
- ▷ **Width** (input_control) extent.x $\leadsto$ integer
Width of image.
Default: 512
Suggested values: Width $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Width (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Height** (input_control) extent.y $\leadsto$ integer
Height of image.
Default: 512
Suggested values: Height $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Height (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **PointerRed** (input_control) pointer $\leadsto$ integer
Pointer to the first gray value of the first channel.
- ▷ **PointerGreen** (input_control) pointer $\leadsto$ integer
Pointer to the first gray value of the second channel.
- ▷ **PointerBlue** (input_control) pointer $\leadsto$ integer
Pointer to the first gray value of the third channel.
- ▷ **ClearProc** (input_control) pointer $\leadsto$ integer
Pointer to the procedure re-releasing the memory of the image when deleting the object.
Default: 0

Example

```
void NewImage(Hobject *new)
{
    unsigned char *image_red;
    unsigned char *image_green;
    unsigned char *image_blue;
    int r, c;
    image_red = malloc(640*480);
    image_green = malloc(640*480);
    image_blue = malloc(640*480);
    for (r=0; r<480; r++)
        for (c=0; c<640; c++)
        {
            image_red[r*640+c] = c % 255;
            image_green[r*640+c] = (c+64) % 255;
            image_blue[r*640+c] = (c+128) % 255;
        }
    gen_image3_extern(new, "byte", 640, 480, (Hlong) image_red, \
(Hlong) image_green, (Hlong) image_blue, (Hlong) free);
}
```

Result

The operator `gen_image3_extern` returns the value 2 (`H_MSG_TRUE`) if the parameter values are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

gen_image_const (: Image : Type, Width, Height :)
--

Create an image with constant gray value.

The operator `gen_image_const` creates an image of the indicated size. The width and height of the image are determined by `Width` and `Height`. HALCON supports the following image types:

'byte' 1 byte per pixel, unsigned

Value range: (0..255)

'int1' 1 byte per pixel, signed

Value range: (-128..127)

'uint2' 2 bytes per pixel, unsigned

Value range: (0..65535)

'int2' 2 bytes per pixel, signed

Value range: (-32768..32767)

'int4' 4 bytes per pixel, signed

Value range: (-2147483648..2147483647)

'int8' 8 bytes per pixel, signed (only available on 64 bit systems)

Value range: (-9223372036854775808..9223372036854775807)

'real' 4 bytes per pixel, floating point

Value range: (-3.4e38..3.4e38)

Precision: 6 significant decimal digits

'complex' Two matrices of type 'real'

'vector_field_relative' Two matrices of type 'real'

Interpretation: Vectors

'vector_field_absolute' Two matrices of type 'real'

Interpretation: Absolute coordinates

'direction' 1 byte per pixel, unsigned

Value range: (0..179)

Interpretation: Angle divided by two

Attention: The values 180..254 are automatically set to the value 255, which is interpreted as undefined angle.

'cyclic' 1 byte per pixel, unsigned, cyclic arithmetics

Value range: (0..255)

With the operator `set_system('init_new_image', <'true'/'false'>)`, it can be controlled whether the created image is initialized with 0 or not.

Parameters

- ▷ **Image** (output_object) image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Created image with new image matrix.
- ▷ **Type** (input_control) string $\leadsto$ string
Pixel type.
Default: 'byte'
List of values: Type $\in$ {'byte', 'direction', 'cyclic', 'int1', 'int2', 'uint2', 'int4', 'int8', 'real', 'complex', 'vector_field_absolute', 'vector_field_relative'}
- ▷ **Width** (input_control) extent.x $\leadsto$ integer
Width of image.
Default: 512
Suggested values: Width $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Width (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Height** (input_control) extent.y $\leadsto$ integer
Height of image.
Default: 512
Suggested values: Height $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Height (lin)}$
Minimum increment: 1
Recommended increment: 10

Example

```
gen_image_const (&New, "byte", width, height);
get_image_pointer1 (New, (Hlong*) &pointer, type, &width, &height);
for (row=0; row<height-1; row++)
{
    for (col=0; col<width-1; col++)
    {
        pointer[row*width+col] = (row + col) % 256;
    }
}
```

Result

If the parameter values are correct, the operator `gen_image_const` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
gen_image_gray_ramp ( : ImageGrayRamp : Alpha, Beta, Mean, Row,
                      Column, Width, Height : )
```

Create a gray value ramp.

The operator `gen_image_gray_ramp` creates a gray value ramp according to the following equation:

$$\text{ImageGrayRamp}(r, c) = \text{Alpha}(r - \text{Row}) + \text{Beta}(c - \text{Column}) + \text{Mean}$$

The size of the image is determined by `Width` and `Height`. The gray values are of the type 'byte'. Gray values outside the valid area are clipped.

Parameters

- ▷ **ImageGrayRamp** (output_object) image $\rightsquigarrow$ object : byte
Created image with new image matrix.
- ▷ **Alpha** (input_control) real $\rightsquigarrow$ real
Gradient in line direction.
Default: 1.0
Suggested values: Alpha $\in \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}$
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Beta** (input_control) real $\rightsquigarrow$ real
Gradient in column direction.
Default: 1.0
Suggested values: Beta $\in \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}$
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Mean** (input_control) real $\rightsquigarrow$ real
Mean gray value.
Default: 128
Suggested values: Mean $\in \{0.0, 20.0, 40.0, 60.0, 80.0, 100.0, 120.0, 140.0, 160.0, 180.0, 200.0, 220.0, 255.0\}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Row** (input_control) point.y $\rightsquigarrow$ integer
Line index of reference point.
Default: 256
Suggested values: Row $\in \{128, 256, 512, 1024\}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Column** (input_control) point.x $\rightsquigarrow$ integer
Column index of reference point.
Default: 256
Suggested values: Column $\in \{128, 256, 512, 1024\}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Width** (input_control) extent.x $\rightsquigarrow$ integer
Width of image.
Default: 512
Suggested values: Width $\in \{128, 256, 512, 1024\}$
Value range: $1 \leq \text{Width (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Height** (input_control) extent.y $\rightsquigarrow$ integer
Height of image.
Default: 512
Suggested values: Height $\in \{128, 256, 512, 1024\}$
Value range: $1 \leq \text{Height (lin)}$
Minimum increment: 1
Recommended increment: 10

Result

If the parameter values are correct `gen_image_gray_ramp` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
gen_image_interleaved ( : ImageRGB : PixelPointer, ColorFormat,
    OriginalWidth, OriginalHeight, Alignment, Type, ImageWidth,
    ImageHeight, StartRow, StartColumn, BitsPerChannel, BitShift : )
```

Create a three-channel image from a pointer to the interleaved pixels.

The operator `gen_image_interleaved` creates a three-channel image from an input image, whose pixels are stored line-sequentially in `PixelPointer`. The size of the input image has to be passed in `OriginalWidth` and `OriginalHeight`, the format of the interleaved pixels in `ColorFormat`.

The output image will be sized `ImageWidth` × `ImageHeight`. Together with the coordinates of upper left corner `StartRow` and `StartColumn` any section of the input image can be extracted. When a 0 is passed to `ImageWidth`, `ImageHeight`, `StartRow`, and `StartColumn`, the output image will have the same dimensions as the input image.

Note that the image type `Type` (see `gen_image_const`) of the output image `ImageRGB` has to be chosen such that the whole range of possible color values of the input image can be represented. I.e. `gen_image_interleaved` does not allow to create a byte image from an input image with `ColorFormat` `'rgb48'`.

When the formats `'rgb48'`, `'bgr48'`, `'rgbx64'`, and `'bgrx64'` do not use the full range of 16 bits per channel and pixel, the number of actually used bits should be passed in `BitsPerChannel`. Furthermore, the pixel values of the input image can be shifted by `BitShift` bits to the right.

The fourth channel of four-channel input images in the formats `'rgbx'`, `'bgrx'`, `'rgbx64'`, and `'bgrx64'` is simply discarded.

The storage for the new image is newly created by HALCON. Thus, it can be released after the call. Note that how to pass a pointer value depends on the used operator signature and programming environment. Make sure to pass the actual memory address where the image data is stored, not the address of a pointer variable. Care must be taken not to truncate 64-bit pointers on 64-bit architectures.

Possible values for `ColorFormat`:

'rgb555': 16 bit rgb triple (5 bit per pixel and channel), the padding bit (X) being the first bit. The bit pattern is XRRRRRGGIGGGBBBBB.

'bgr555': 16 bit bgr triple (5 bit per pixel and channel), the padding bit (X) being the first bit. The bit pattern is XBBBBBGGIGGGRRRRR.

'rgb5551': 16 bit rgb triple (5 bit per pixel and channel), the padding bit (X) being the last bit. The bit pattern is RRRRRGGGIGGGBBBBBX.

'bgr5551': 16 bit bgr triple (5 bit per pixel and channel), the padding bit (X) being the last bit. The bit pattern is BBBBGGGIGGRRRRRX.

'rgb565': 16 bit rgb triple (5 bit per pixel and channel, 6 bit for the green channel). The bit pattern is RRRRRGGGIGGGBBBBB.

'bgr565': 16 bit bgr triple (5 bit per pixel and channel, 6 bit for the green channel). The bit pattern is BBBB-BGGGIGGRRRRR.

'rgb': 24 bit rgb triple (8 bit per pixel and channel)

'bgr': 24 bit bgr triple (8 bit per pixel and channel)

'rgbx': 32 bit rgb quadruple (8 bit per pixel and channel)

'bgrx': 32 bit bgr quadruple (8 bit per pixel and channel)

'rgb48': 48 bit rgb triple (16 bit per pixel and channel)

'bgr48': 48 bit bgr triple (16 bit per pixel and channel)

'rgbx64': 64 bit rgb quadruple (16 bit per pixel and channel)

'bgrx64': 64 bit bgr quadruple (16 bit per pixel and channel)

The values *'rgb555'*, *'bgr555'*, *'rgb565'*, *'bgr565'*, *'rgb5551'* and *'bgr5551'* can be used with the suffix *'le'* (Little Endian: Lower byte is expected first) or - which is the default if the suffix is omitted - *'be'* (Big Endian: Higher byte is expected first). For example, the bit pattern for `ColorFormat = 'rgb555'` is XRRRRRRGGIGGGBBBBB, while the bit pattern for `ColorFormat = 'rgb555le'` is GGGBBBBBIXRRRRRRGG.

Attention

`gen_image_interleaved` does not check whether the `PixelPointer` is valid or not. Thus, it must be ensured by the user that it is valid. Otherwise, the program may crash!

Parameters

- ▷ **ImageRGB** (output_object) image $\leadsto$ object : byte / uint2
Created image with new image matrix.
- ▷ **PixelPointer** (input_control) pointer $\leadsto$ integer
Pointer to interleaved pixels.
- ▷ **ColorFormat** (input_control) string $\leadsto$ string
Format of the input pixels.
Default: 'rgb'
List of values: `ColorFormat` $\in$ {'rgb', 'bgr', 'rgbx', 'bgrx', 'rgb48', 'bgr48', 'rgbx64', 'bgrx64', 'rgb555', 'bgr555', 'rgb565', 'bgr565', 'rgb555le', 'bgr555le', 'rgb565le', 'bgr565le', 'rgb555be', 'bgr555be', 'rgb565be', 'bgr565be', 'rgb5551', 'bgr5551', 'rgb5551le', 'bgr5551le', 'rgb5551be', 'bgr5551be'}
- ▷ **OriginalWidth** (input_control) extent.x $\leadsto$ integer
Width of input image.
Default: 512
Suggested values: `OriginalWidth` $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{OriginalWidth}$ (lin)
Minimum increment: 1
Recommended increment: 10
- ▷ **OriginalHeight** (input_control) extent.y $\leadsto$ integer
Height of input image.
Default: 512
Suggested values: `OriginalHeight` $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{OriginalHeight}$ (lin)
Minimum increment: 1
Recommended increment: 10
- ▷ **Alignment** (input_control) integer $\leadsto$ integer
Reserved.
- ▷ **Type** (input_control) string $\leadsto$ string
Pixel type of output image.
Default: 'byte'
List of values: `Type` $\in$ {'byte', 'uint2'}

- ▷ **ImageWidth** (input_control)rectangle.extent.x $\leadsto$ *integer*
Width of output image.
Default: 0
Suggested values: ImageWidth $\in \{128, 256, 512, 1024\}$
Value range: $0 \leq \text{ImageWidth}$ (lin)
Minimum increment: 1
Recommended increment: 10
- ▷ **ImageHeight** (input_control)rectangle.extent.y $\leadsto$ *integer*
Height of output image.
Default: 0
Suggested values: ImageHeight $\in \{128, 256, 512, 1024\}$
Value range: $0 \leq \text{ImageHeight}$ (lin)
Minimum increment: 1
Recommended increment: 10
- ▷ **StartRow** (input_control)rectangle.origin.y $\leadsto$ *integer*
Line number of upper left corner of desired image part.
Default: 0
Suggested values: StartRow $\in \{-1, 0\}$
- ▷ **StartColumn** (input_control)rectangle.origin.x $\leadsto$ *integer*
Column number of upper left corner of desired image part.
Default: 0
Suggested values: StartColumn $\in \{-1, 0\}$
- ▷ **BitsPerChannel** (input_control) integer $\leadsto$ *integer*
Number of used bits per pixel and channel of the output image (-1: All bits are used).
Default: -1
Suggested values: BitsPerChannel $\in \{5, 8, 10, 12, 16, -1\}$
- ▷ **BitShift** (input_control) integer $\leadsto$ *integer*
Number of bits that the color values of the input pixels are shifted to the right (only uint2 images).
Default: 0
Suggested values: BitShift $\in \{0, 2, 4, 6\}$

Result

If the parameter values are correct, the operator `gen_image_interleaved` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Successors

Module

Foundation

gen_image_proto (Image : ImageCleared : Grayval :)

Create an image with a specified constant gray value.

`gen_image_proto` creates an output image [ImageCleared](#) with the constant gray value [Grayval](#). If the input image is of type `direction`, gray values in result image that are not in the value range that is valid for `direction` images are set to the value 255 to mark them as invalid. [ImageCleared](#) has the same dimensions and pixel type as the input image [Image](#).

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image.
- ▷ **ImageCleared** (output_object) image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Image with constant gray value.
- ▷ **Grayval** (input_control) number $\leadsto$ real / integer
Gray value to be used for the output image.
Default: 0
Suggested values: Grayval $\in$ {0, 1, 2, 5, 10, 16, 32, 64, 128, 253, 254, 255}

Result

gen_image_proto returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
gen_image_surface_first_order ( : ImageSurface : Type, Alpha,
    Beta, Gamma, Row, Column, Width, Height : )
```

Create a tilted gray surface with first order polynomial.

The operator `gen_image_surface_first_order` creates a tilted gray value surface according to the following equation:

$$\begin{aligned} \text{ImageSurface}(r, c) &= \text{Alpha}(r - \text{Row}) \\ &+ \text{Beta}(c - \text{Column}) \\ &+ \text{Gamma} \end{aligned}$$

The size of the image is determined by `Width` and `Height`. The parameters `Row` and `Column` define the reference point of the created gray surface. If `fit_surface_first_order` was used to determine the parameters of the gray surface, this reference point should correspond to the center of gravity that is used in the surface equation (see `fit_surface_first_order`). Its coordinates can be computed as follows:

```
intersection(ROI, Image, RegionIntersection)
fit_surface_first_order(RegionIntersection, Image, Algorithm,
Iterations, ClippingFactor, Alpha, Beta, Gamma)
area_center(RegionIntersection, Area, Row, Column)
gen_image_surface_first_order(ImageSurface, Type, Alpha, Beta,
Gamma, Row, Column, Width, Height)
```

The gray values are of the type `Type` (see `gen_image_const` for a detailed description of the pixel types). Gray values outside the valid area are clipped.

Parameters

- ▷ **ImageSurface** (output_object) image $\rightsquigarrow$ object : byte / uint2 / real
Created image with new image matrix.
- ▷ **Type** (input_control) string $\rightsquigarrow$ string
Pixel type.
Default: 'byte'
List of values: Type $\in$ {'byte', 'uint2', 'real'}
- ▷ **Alpha** (input_control) number $\rightsquigarrow$ real
First order coefficient in vertical direction.
Default: 1.0
Suggested values: Alpha $\in$ {-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0}
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Beta** (input_control) number $\rightsquigarrow$ real
First order coefficient in horizontal direction.
Default: 1.0
Suggested values: Beta $\in$ {-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0}
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Gamma** (input_control) number $\rightsquigarrow$ real
Zero order coefficient.
Default: 1.0
Suggested values: Gamma $\in$ {-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0}
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Row** (input_control) number $\rightsquigarrow$ real
Row coordinate of the reference point of the surface.
Default: 256.0
Suggested values: Row $\in$ {0.0, 128.0, 256.0, 512.0}
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Column** (input_control) number $\rightsquigarrow$ real
Column coordinate of the reference point of the surface.
Default: 256.0
Suggested values: Column $\in$ {0.0, 128.0, 256.0, 512.0}
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Width** (input_control) extent.x $\rightsquigarrow$ integer
Width of image.
Default: 512
Suggested values: Width $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Width (lin)}$
Minimum increment: 1
Recommended increment: 10
- ▷ **Height** (input_control) extent.y $\rightsquigarrow$ integer
Height of image.
Default: 512
Suggested values: Height $\in$ {128, 256, 512, 1024}
Value range: $1 \leq \text{Height (lin)}$
Minimum increment: 1
Recommended increment: 10

Result

If the parameter values are correct `gen_image_surface_first_order` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

[gen_image_gray_ramp](#), [gen_image_surface_second_order](#), [gen_image_const](#)

Module

Foundation

```
gen_image_surface_second_order ( : ImageSurface : Type, Alpha,
    Beta, Gamma, Delta, Epsilon, Zeta, Row, Column, Width,
    Height : )
```

Create a curved gray surface with second order polynomial.

The operator `gen_image_surface_second_order` creates a curved gray value surface according to the following equation:

$$\begin{aligned}
 \text{ImageSurface}(r, c) = & \text{Alpha}(r - \text{Row})^2 \\
 & + \text{Beta}(c - \text{Column})^2 \\
 & + \text{Gamma}(r - \text{Row}) * (c - \text{Column}) \\
 & + \text{Delta}(r - \text{Row}) \\
 & + \text{Epsilon}(c - \text{Column}) \\
 & + \text{Zeta}
 \end{aligned}$$

The size of the image is determined by `Width` and `Height`. The parameters `Row` and `Column` define the reference point of the created gray surface. If `fit_surface_second_order` was used to determine the parameters of the gray surface, this reference point should correspond to the center of gravity that is used in the surface equation (see `fit_surface_second_order`). Its coordinates can be computed as follows:

```
intersection(ROI, Image, RegionIntersection)
fit_surface_second_order(RegionIntersection, Image, Algorithm,
Iterations, ClippingFactor, Alpha, Beta, Gamma, Delta, Epsilon,
Zeta)
area_center(RegionIntersection, Area, Row, Column)
gen_image_surface_second_order(ImageSurface, Type, Alpha, Beta,
Gamma, Delta, Epsilon, Zeta, Row, Column, Width, Height)
```

The gray values are of the type `Type` (see `gen_image_const` for a detailed description of the pixel types). Gray values outside the valid area are clipped.

Parameters

- ▷ **ImageSurface** (output_object) image $\leadsto$ object : byte / uint2 / real
Created image with new image matrix.
- ▷ **Type** (input_control) string $\leadsto$ string
Pixel type.
Default: 'byte'
List of values: Type $\in$ {'byte', 'uint2', 'real' }

- ▷ **Alpha** (input_control) number $\leadsto$ *real*
 Second order coefficient in vertical direction.
Default: 1.0
Suggested values: Alpha $\in \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}$
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Beta** (input_control) number $\leadsto$ *real*
 Second order coefficient in horizontal direction.
Default: 1.0
Suggested values: Beta $\in \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}$
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Gamma** (input_control) number $\leadsto$ *real*
 Mixed second order coefficient.
Default: 1.0
Suggested values: Gamma $\in \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}$
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Delta** (input_control) number $\leadsto$ *real*
 First order coefficient in vertical direction.
Default: 1.0
Suggested values: Delta $\in \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}$
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Epsilon** (input_control) number $\leadsto$ *real*
 First order coefficient in horizontal direction.
Default: 1.0
Suggested values: Epsilon $\in \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}$
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Zeta** (input_control) number $\leadsto$ *real*
 Zero order coefficient.
Default: 1.0
Suggested values: Zeta $\in \{-2.0, -1.0, -0.5, -0.0, 0.5, 1.0, 2.0\}$
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Row** (input_control) number $\leadsto$ *real*
 Row coordinate of the reference point of the surface.
Default: 256.0
Suggested values: Row $\in \{0.0, 128.0, 256.0, 512.0\}$
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Column** (input_control) number $\leadsto$ *real*
 Column coordinate of the reference point of the surface.
Default: 256.0
Suggested values: Column $\in \{0.0, 128.0, 256.0, 512.0\}$
Minimum increment: 0.000001
Recommended increment: -0.005
- ▷ **Width** (input_control) extent.x $\leadsto$ *integer*
 Width of image.
Default: 512
Suggested values: Width $\in \{128, 256, 512, 1024\}$
Value range: $1 \leq \text{Width (lin)}$
Minimum increment: 1
Recommended increment: 10

- ▷ **Height** (input_control) extent.y $\leadsto$ *integer*
 Height of image.
Default: 512
Suggested values: Height $\in \{128, 256, 512, 1024\}$
Value range: $1 \leq \text{Height (lin)}$
Minimum increment: 1
Recommended increment: 10

Example

```
* Adjust an inhomogeneous illumination
* using gen_image_surface_second_order
read_image (Image, 'cap_illumination/cap_illumination_01')
get_image_size (Image, Width, Height)
gen_circle (Circle, 495, 630, 350.5)
difference (Image, Circle, RegionDifference)
fit_surface_second_order (RegionDifference, Image, 'regression', 5, 2, \
                          Alpha, Beta, Gamma, Delta, Epsilon, Zeta)
area_center (RegionDifference, Area, Row, Column)
gen_image_surface_second_order (ImageSurface, 'byte', Alpha, Beta, \
                               Gamma, Delta, Epsilon, Zeta, Row, Column, \
                               Width, Height)
sub_image (Image, ImageSurface, ImageSub, 1, 128)
```

Result

If the parameter values are correct `gen_image_surface_second_order` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
interleave_channels (
    MultichannelImage : InterleavedImage : PixelFormat, RowBytes,
    Alpha : )
```

Create an interleaved image from a multichannel image.

The operator `interleave_channels` creates an [InterleavedImage](#) from the input [MultichannelImage](#) containing three or four channels. This is useful to prepare a color image for visualization, e.g., by converting it to a .NET Bitmap.

Pixel format

The format of the pixels in [InterleavedImage](#) is specified with [PixelFormat](#). Possible formats are 'rgb', 'rgba', 'argb', 'bgr', 'bgra', and 'abgr' for BYTE images and 'rgb48', 'bgr48', 'rgba64', 'bgra64', 'argb64' and 'abgr64' for UINT2 images, where 'a' denotes the 4th ('alpha') channel. Be aware that, in contrast to [gen_image_interleaved](#), LittleEndian byte ordering is used in [PixelFormat](#).

Alpha channel

The alpha channel can be defined in the following ways:

channels	domain	
3	not specified/full	Value of Alpha is set for the complete image.
3	reduced	Inside the domain: alpha is set to Alpha . Outside the domain: alpha is set to zero.
4		Alpha is set to the respective value of the fourth channel, domain and Alpha are ignored.

Row alignment

The number of bytes between the beginning of two rows in the output image can be set in [RowBytes](#), e.g., to fulfill specific alignment criteria. Set [RowBytes](#) to 'match' if no additional padding is required. [RowBytes](#) must be at least the number of bytes in [PixelFormat](#) times the width of [MultichannelImage](#).

Parameters

- ▷ **MultichannelImage** (input_object) multichannel-image $\leadsto$ object : byte
Input multichannel image.
- ▷ **InterleavedImage** (output_object) singlechannelimage $\leadsto$ object : byte
Output interleaved image.
- ▷ **PixelFormat** (input_control) string $\leadsto$ string
Target format for InterleavedImage.
Default: 'rgba'
List of values: PixelFormat $\in$ {'rgb', 'bgr', 'rgba', 'abgr', 'argb', 'bgra', 'rgb48', 'bgr48', 'rgba64', 'bgra64', 'argb64', 'abgr64'}
- ▷ **RowBytes** (input_control) integer $\leadsto$ string / integer
Number of bytes in a row of the output image.
Default: 'match'
Suggested values: RowBytes $\in$ {'match'}
- ▷ **Alpha** (input_control) integer $\leadsto$ integer
Alpha value for three channel input images.
Default: 255
Suggested values: Alpha $\in$ {255, 0}

Example

```
HTuple type, width, height;
HImage patras = new HImage("patras");

HImage interleaved = patras.InterleaveChannels("argb", "match", 255);
IntPtr ptr = interleaved.GetImagePointer1(out type, out width, out height);

Image img = new Bitmap(width/4, height, width,
    PixelFormat.Format32bppArgb, ptr);

pictureBox.Image = img;
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Foundation

region_to_bin (Region : BinImage : ForegroundGray, BackgroundGray,
Width, Height :)

Convert a region into a binary byte-image.

`region_to_bin` converts the input region given in `Region` into a 'byte'-image and assigns a gray value of `ForegroundGray` to all pixels in the region. If the input region is larger than the generated image, it is clipped at the image borders. The background is set to `BackgroundGray`.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ *object*
Regions to be converted.
- ▷ **BinImage** (output_object) image $\leadsto$ *object* : byte
Result image of dimension Width $\times$ Height containing the converted regions.
- ▷ **ForegroundGray** (input_control) integer $\leadsto$ *integer*
Gray value in which the regions are displayed.
Default: 255
Suggested values: ForegroundGray $\in$ {0, 1, 50, 100, 128, 150, 200, 254, 255}
Value range: $0 \leq \text{ForegroundGray} \leq 255$ (lin)
Recommended increment: 1
- ▷ **BackgroundGray** (input_control) integer $\leadsto$ *integer*
Gray value in which the background is displayed.
Default: 0
Suggested values: BackgroundGray $\in$ {0, 1, 50, 100, 128, 150, 200, 254, 255}
Value range: $0 \leq \text{BackgroundGray} \leq 255$ (lin)
Recommended increment: 1
- ▷ **Width** (input_control) extent.x $\leadsto$ *integer*
Width of the image to be generated.
Default: 512
Suggested values: Width $\in$ {256, 512, 1024}
Value range: $1 \leq \text{Width} \leq 1024$ (lin)
Minimum increment: 1
Recommended increment: 16
Restriction: Width ≥ 1
- ▷ **Height** (input_control) extent.y $\leadsto$ *integer*
Height of the image to be generated.
Default: 512
Suggested values: Height $\in$ {256, 512, 1024}
Value range: $1 \leq \text{Height} \leq 1024$ (lin)
Minimum increment: 1
Recommended increment: 16
Restriction: Height ≥ 1

Complexity

$O(2 * \text{Height} * \text{Width})$.

Result

`region_to_bin` always returns 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result', <Result>)` and the behavior in case of an empty input region via `set_system('empty_region_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_image_proto , paint_gray	
	Module
Foundation	

region_to_label (Region : ImageLabel : Type, Width, Height :)
--

Convert regions to a label image.

`region_to_label` converts the input regions into a label image according to their index (1..*n*), i.e., the first region is painted with the gray value 1, the second the gray value 2, etc. Only positive gray values are used. For 'byte'-images the index is entered modulo 256.

Regions larger than the generated image are clipped appropriately. If regions overlap the regions with the higher image are entered (i.e., they are painted in the order in which they are contained in the input regions). If so desired, the regions can be made non-overlapping by calling [expand_region](#).

The background, i.e., the area not covered by any regions, is set to 0. This can be used to test in which image range no region is present.

	Parameters
▷ Region (input_object) region(-array) $\leadsto$ object Regions to be converted. ▷ ImageLabel (output_object) image $\leadsto$ object : byte / int2 / int4 Result image of dimension Width $\times$ Height containing the converted regions. ▷ Type (input_control) string $\leadsto$ string Pixel type of the result image. Default: 'int2' List of values: Type $\in$ {'byte', 'int2', 'int4', 'int8'} ▷ Width (input_control) extent.y $\leadsto$ integer Width of the image to be generated. Default: 512 Suggested values: Width $\in$ {64, 128, 256, 512, 1024} Value range: $1 \leq \text{Width} \leq 1024$ (lin) Minimum increment: 1 Recommended increment: 16 Restriction: Width ≥ 1 ▷ Height (input_control) extent.x $\leadsto$ integer Height of the image to be generated. Default: 512 Suggested values: Height $\in$ {64, 128, 256, 512, 1024} Value range: $1 \leq \text{Height} \leq 1024$ (lin) Minimum increment: 1 Recommended increment: 16 Restriction: Height ≥ 1	

	Complexity
$O(2 * \text{Height} * \text{Width})$.	

	Result
<code>region_to_label</code> always returns 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via <code>set_system('no_object_result', <Result>)</code> and the behavior in case of an empty input region via <code>set_system('empty_region_result', <Result>)</code>. If necessary, an exception is raised.	

	Execution Information
--	-----------------------

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

region_to_mean (Regions, Image : ImageMean : :)
--

Paint regions with their average gray value.

`region_to_mean` returns an image in which the regions [Regions](#) are painted with their average gray value based on the image [Image](#). This operator is mainly intended to visualize segmentation results.

Parameters

- ▷ **Regions** (input_object) `region(-array) ~> object`
Input regions.
- ▷ **Image** (input_object) `(multichannel-)image ~> object : byte / uint2`
original gray-value image.
- ▷ **ImageMean** (output_object) `image ~> object : byte / uint2`
Result image with painted regions.

Example

```
read_image (Image, 'fabrik')
regiongrowing (Image, Regions, 3, 3, 6, 100)
region_to_mean (Regions, Image, Disp)
dev_display (Disp)
dev_set_draw ('margin')
dev_display (Regions)
```

Result

`region_to_mean` returns 2 (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on channel level.

15.5 Domain

add_channels (Regions, Image : GrayRegions : :)

Add gray values to regions.

The operator `add_channels` creates an array of images `GrayRegions` with an element for every input region in `Regions`. These images correspond to the input image `Image` with a reduced domain, namely the intersection of the definition domain of the input image with the region. Thus, the new definition domain can be a subset of the region. Thereby the size of the image matrix is not changed and all channels of `Image` are adopted.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Input regions (without pixel values).
- ▷ **Image** (input_object) (multichannel-)image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image with pixel values for regions.
- ▷ **GrayRegions** (output_object) image(-array) $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Output image(s) with regions and pixel values (one image per input region).
Number of elements: Regions == GrayRegions

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

See also

`full_domain`, `get_domain`, `intersection`

Module

Foundation

change_domain (Image, NewDomain : ImageNew : :)

Change definition domain of an image.

The operator `change_domain` uses the indicated region as the new definition domain. Unlike the operator `reduce_domain` it does not form the intersection of the previous definition domain, i.e., the size of the matrix is not changed. This implies in particular, that the region must not exceed the image matrix, otherwise using such inconsistent iconic objects during subsequent operations will likely lead to errors or system crashes.

Attention

Due to running time the transferred region is not checked for consistency (i.e., whether it fits with the image matrix). Incorrect regions lead to system hang-ups during subsequent operations.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image.
- ▷ **NewDomain** (input_object) region $\leadsto$ *object*
New definition domain.
- ▷ **ImageNew** (output_object) image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Image with new definition domain.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

full_domain (Image : ImageFull : :)
--

Expand the domain of an image to maximum.

The operator `full_domain` enters a rectangle with the edge length of the image as new definition domain. This means that all pixels of the matrix are included in further operations. Thus the same definition domain is obtained as by reading or generating an image. The size of the matrix is not changed.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image.
- ▷ **ImageFull** (output_object) image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Image with maximum definition domain.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

rectangle1_domain (Image : ImageReduced : Row1, Column1, Row2, Column2 :)
--

Reduce the domain of an image to a rectangle.

The operator `rectangle1_domain` reduces the definition domain of the given image to the specified rectangle. The size of the matrix is not changed.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image.
- ▷ **ImageReduced** (output_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Image with reduced definition domain.
- ▷ **Row1** (input_control) rectangle.origin.y $\leadsto$ *integer*
Line index of upper left corner of image area.
Default: 100
Suggested values: Row1 $\in$ {10, 20, 50, 100, 200, 300, 500}
Value range: 0 $\leq$ Row1 $\leq$ 1024

- ▷ **Column1** (input_control) rectangle.origin.x $\leadsto$ *integer*
Column index of upper left corner of image area.
Default: 100
Suggested values: Column1 $\in$ {10, 20, 50, 100, 200, 300, 500}
Value range: $0 \leq \text{Column1} \leq 1024$
- ▷ **Row2** (input_control) rectangle.origin.y $\leadsto$ *integer*
Line index of lower right corner of image area.
Default: 200
Suggested values: Row2 $\in$ {10, 20, 50, 100, 200, 300, 500}
Value range: $0 \leq \text{Row2} \leq 1024$
- ▷ **Column2** (input_control) rectangle.origin.x $\leadsto$ *integer*
Column index of lower right corner of image area.
Default: 200
Suggested values: Column2 $\in$ {10, 20, 50, 100, 200, 300, 500}
Value range: $0 \leq \text{Column2} \leq 1024$

reduce_domain (Image, Region : ImageReduced : :)

Reduce the domain of an image.

The operator `reduce_domain` reduces the definition domain of the given image to the indicated region. The new definition domain is calculated as the intersection of the old definition domain with the region. Thus, the new definition domain can be a subset of the region. The size of the matrix is not changed.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image.
- ▷ **Region** (input_object) region $\leadsto$ *object*
New definition domain.
- ▷ **ImageReduced** (output_object) image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Image with reduced definition domain.

15.6 Features

area_center_gray (Regions , Image : : : Area , Row , Column)

Compute the area and center of gravity of a region in a gray value image.

`area_center_gray` computes the area and center of gravity of the regions [Regions](#) that have gray values which are defined by the image [Image](#). This operator is similar to [area_center](#), but in contrast to that operator, the gray values of the image are taken into account while computing the area and center of gravity.

The area A of a region R in the image with the gray values $g(r, c)$ is defined as

$$A = \sum_{(r,c) \in R} g(r, c).$$

This means that the area is defined by the volume of the gray value function $g(r, c)$. The center of gravity is defined by the first two normalized moments of the gray values $g(r, c)$, i.e., by $(m_{1,0}, m_{0,1})$, where

$$m_{p,q} = \frac{1}{A} \sum_{(r,c) \in R} r^p c^q g(r, c).$$

Note, that in the case where the [Area](#) is zero the row and column coordinates of the center of gravity are also set to zero.

Attention

Note that the operator `area_center_gray` only considers the given [Regions](#) and ignores any previously set domain of the input image [Image](#). `area_center_gray` can be executed on OpenCL devices if the device supports the `cl_khr_fp64` and `cl_khr_int64_base_atomics` OpenCL extensions.

Parameters

- ▷ **Regions** (input_object) [region](#)(-array) $\leadsto$ *object*
Region(s) to be examined.
- ▷ **Image** (input_object) [singlechannelimage](#) $\leadsto$ *object* : [byte](#) / [direction](#) / [cyclic](#) / [int1](#) / [int2](#) / [uint2](#) / [int4](#)
/ [real](#)
Gray value image.
- ▷ **Area** (output_control) [real](#)(-array) $\leadsto$ *real*
Gray value volume of the region.
- ▷ **Row** (output_control) [point.y](#)(-array) $\leadsto$ *real*
Row coordinate of the gray value center of gravity.
- ▷ **Column** (output_control) [point.x](#)(-array) $\leadsto$ *real*
Column coordinate of the gray value center of gravity.

Result

`area_center_gray` returns 2 ([H_MSG_TRUE](#)) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via `set_system(:,:, 'no_object_result', <Result>: )`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

```
cooc_feature_image ( Regions, Image : : LdGray,
                    Direction : Energy, Correlation, Homogeneity, Contrast )
```

Calculate a co-occurrence matrix and derive gray value features thereof.

The call of `cooc_feature_image` corresponds to the consecutive execution of the operators [gen_cooc_matrix](#) and [cooc_feature_matrix](#). If several direction matrices of the co-occurrence matrix are to be evaluated consecutively, it is more efficient to generate the matrix via [gen_cooc_matrix](#) and then call the operator [cooc_feature_matrix](#) for the resulting matrix. The parameter [Direction](#) transfers the direction of the neighborhood in angle or 'mean'. In the case of 'mean' the mean value is calculated in all four directions.

Attention

Note that the operator `cooc_feature_image` only considers the given [Regions](#) and ignores any previously set domain of the input image [Image](#).

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Region to be examined.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte
Corresponding gray values.
- ▷ **LdGray** (input_control) integer $\leadsto$ integer
Number of gray values to be distinguished (2^{[LdGray](#)}).
Default: 6
List of values: `LdGray` $\in$ {1, 2, 3, 4, 5, 6, 7, 8}
- ▷ **Direction** (input_control) integer $\leadsto$ integer / string
Direction in which the matrix is to be calculated.
Default: 0
List of values: `Direction` $\in$ {0, 45, 90, 135, 'mean'}
- ▷ **Energy** (output_control) real(-array) $\leadsto$ real
Gray value energy.
- ▷ **Correlation** (output_control) real(-array) $\leadsto$ real
Correlation of gray values.
- ▷ **Homogeneity** (output_control) real(-array) $\leadsto$ real
Local homogeneity of gray values.
- ▷ **Contrast** (output_control) real(-array) $\leadsto$ real
Gray value contrast.

Result

The operator `cooc_feature_image` returns the value 2 (`H_MSG_TRUE`) if an image with defined gray values ('byte') is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system( : : 'no_object_result', <Result> : )`, the behavior in case of empty

region is set via `set_system(:,:, 'empty_region_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

cooc_feature_matrix (CoocMatrix : : : Energy, Correlation,
Homogeneity, Contrast)

Calculate gray value features from a co-occurrence matrix.

The operator `cooc_feature_matrix` calculates from a co-occurrence matrix (`CoocMatrix`) the energy (`Energy`), correlation (`Correlation`), local homogeneity (`Homogeneity`) and contrast (`Contrast`).

The operator `cooc_feature_matrix` calculates the gray value features from the part of the input matrix generated by `gen_cooc_matrix` corresponding to the direction matrix indicated by the parameters `LdGray` and `Direction` according to the following formulae:

- Energy (Measure for image homogeneity):

$$\text{Energy} = \sum_{i,j=0}^{\text{width}} c_{ij}^2$$
- Correlation (Measure for gray value dependencies):

$$\text{Correlation} = \frac{\sum_{i,j=0}^{\text{width}} (i-u_x)(j-u_y)c_{ij}}{s_x s_y}$$
- Local homogeneity:

$$\text{Homogeneity} = \sum_{i,j=0}^{\text{width}} \frac{1}{1+(i-j)^2} c_{ij}$$
- Contrast (Measure for the size of the intensity differences):

$$\text{Contrast} = \sum_{i,j=0}^{\text{width}} (i-j)^2 c_{ij}$$

where

width = Width of `CoocMatrix`,

c_{ij} Entry of co-occurrence matrix,

$$u_x = \sum_{i,j=0}^{\text{width}} i * c_{ij},$$

$$u_y = \sum_{i,j=0}^{\text{width}} j * c_{ij},$$

$$s_x^2 = \sum_{i,j=0}^{\text{width}} (i - u_x)^2 * c_{ij},$$

$$s_y^2 = \sum_{i,j=0}^{\text{width}} (i - u_y)^2 * c_{ij}.$$

Attention

The region of the input image is disregarded.

Parameters

- ▷ **CoocMatrix** (input_object) singlechannelimage(-array) $\leadsto$ object : real
Co-occurrence matrix.
- ▷ **Energy** (output_control) real $\leadsto$ real
Homogeneity of the gray values.
- ▷ **Correlation** (output_control) real $\leadsto$ real
Correlation of gray values.
- ▷ **Homogeneity** (output_control) real $\leadsto$ real
Local homogeneity of gray values.
- ▷ **Contrast** (output_control) real $\leadsto$ real
Gray value contrast.

Result

The operator `cooc_feature_matrix` returns the value 2 (`H_MSG_TRUE`) if an image with defined gray values is passed and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(, 'no_object_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

elliptic_axis_gray (Regions, Image : : : Ra, Rb, Phi)

Compute the orientation and major axes of a region in a gray value image.

The operator `elliptic_axis_gray` calculates the length of the axes `Ra` and `Rb` and the orientation `Phi` of the ellipse having the “same orientation” and the “aspect ratio” as the input region in `Regions`. Therefore, gray value moments which are derived from the `Image` are used. Several input regions can be passed in `Regions` as tuples. The length of the major axis `Ra` and the minor axis `Rb` as well as the orientation of the major axis with regard to the x-axis (`Phi`) are determined. The angle is returned in radians. The calculation is done analogously to `elliptic_axis`. The only difference is that in `elliptic_axis_gray` the gray value moments are used instead of the region moments. For the definition of the gray value moments, see `area_center_gray`.

Note, that in the case where the gray value area is zero the length of the axes `Ra` and `Rb` as well as the orientation `Phi` are also set to zero.

Attention

Note that the operator `elliptic_axis_gray` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Region(s) to be examined.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Gray value image.

- ▷ **Ra** (output_control) real(-array) $\leadsto$ real
Major axis of the region.
- ▷ **Rb** (output_control) real(-array) $\leadsto$ real
Minor axis of the region.
- ▷ **Phi** (output_control) angle.rad(-array) $\leadsto$ real
Angle enclosed by the major axis and the x-axis.

Result

`elliptic_axis_gray` returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via `set_system(:,:, 'no_object_result', <Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

`area_center_gray`

Module

Foundation

entropy_gray (Regions, Image : : : Entropy, Anisotropy)

Determine the entropy and anisotropy of images.

The operator `entropy_gray` creates the histogram of relative frequencies of the gray values in the input image and calculates from these frequencies the entropy and the anisotropy coefficient for each region from `Regions` according to the following formulae:

Entropy:

$$Entropy = - \sum_0^{255} rel[i] * \log_2(rel[i])$$

Anisotropy coefficient:

$$Anisotropy = \frac{\sum_0^k rel[i] * \log_2(rel[i])}{Entropy}$$

where

$rel[i]$ = Histogram of relative gray value frequencies

i = Gray value of input image (0...255)

k = Smallest possible gray value with $\sum_0^k rel[i] \geq 0.5$

Attention

Note that the operator `entropy_gray` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ *object*
Regions where the features are to be determined.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ *object* : byte
Gray value image.
- ▷ **Entropy** (output_control) real(-array) $\leadsto$ *real*
Information content (entropy) of the gray values.
Assertion: $0 \leq \text{Entropy} \ \&\& \ \text{Entropy} \leq 8$
- ▷ **Anisotropy** (output_control) real(-array) $\leadsto$ *real*
Measure of the symmetry of gray value distribution.

Complexity

If F is the area of the region the runtime complexity is $O(F + 255)$.

Result

The operator `entropy_gray` returns the value 2 (`H_MSG_TRUE`) if an image with defined gray values is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system( : : 'no_object_result', <Result> : )`, the behavior in case of empty region is set via `set_system( : : 'empty_region_result', <Result> : )`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

estimate_noise (Image : : Method, Percent : Sigma)

Estimate the image noise from a single image.

The operator `estimate_noise` estimates the standard deviation of additive noise within the domain of the image that is passed in `Image`. The standard deviation is returned in `Sigma`.

To estimate the noise, one of the following four methods can be selected in `Method`:

- *'foerstner'*: If `Method` is set to *'foerstner'*, first for each pixel a homogeneity measure is computed based on the first derivatives of the gray values of `Image`. By thresholding the homogeneity measure one obtains the homogeneous regions in the image. The threshold is computed based on a starting value for the image noise. The starting value is obtained by applying the method *'immerkaer'* (see below) in the first step. It is assumed that the gray value fluctuations within the homogeneous regions are solely caused by the image noise. Furthermore it is assumed that the image noise is Gaussian distributed. The average homogeneity measure within the homogeneous regions is then used to calculate a refined estimate for the image noise. The refined estimate leads to a new threshold for the homogeneity. The described process is iterated until the estimated image noise remains constant between two successive iterations. Finally, the standard deviation of the estimated image noise is returned in `Sigma`.

Note that in some cases the iteration falsely converges to the value 0. This happens, for example, if the gray value histogram of the input image contains gaps that are caused either by an automatic radiometric scaling of the camera or frame grabber, respectively, or by a manual spreading of the gray values using a scaling factor > 1 .

Also note that the result obtained by this method is independent of the value passed in `Percent`.

- *'immerkaer'*: If **Method** is set to *'immerkaer'*, first the following filter mask is applied to the input image:

$$M = \begin{vmatrix} 1 & -2 & 1 \\ -2 & 4 & -2 \\ 1 & -2 & 1 \end{vmatrix}.$$

The advantage of this method is that M is almost insensitive to image structure but only depends on the noise in the image. Assuming a Gaussian distributed noise, its standard deviation is finally obtained as

$$\text{Sigma} = \sqrt{\frac{\pi}{2}} \frac{1}{6N} \sum_{\text{Image}} |\text{Image} * M|,$$

where N is the number of image pixels to which M is applied. Note that the result obtained by this method is independent of the value passed in **Percent**.

- *'least_squares'*: If **Method** is set to *'least_squares'*, the fluctuations of the gray values with respect to a locally fitted gray value plane are used to estimate the image noise. First, a homogeneity measure is computed based on the first derivatives of the gray values of **Image**. Homogeneous image regions are determined by selecting the **Percent** percent most homogeneous pixels in the domain of the input image, i.e., pixels with small magnitudes of the first derivatives. For each homogeneous pixel a gray value plane is fitted to its 3×3 neighborhood. The differences between the gray values within the 3×3 neighborhood and the locally fitted plane are used to estimate the standard deviation of the noise. Finally, the average standard deviation over all homogeneous pixels is returned in **Sigma**.
- *'mean'*: If **Method** is set to *'mean'*, the noise estimation is based on the difference between the input image and a noiseless version of the input image. First, a homogeneity measure is computed based on the first derivatives of the gray values of **Image**. Homogeneous image regions are determined by selecting the **Percent** percent most homogeneous pixels in the domain of the input image, i.e., pixels with small magnitudes of the first derivatives. A mean filter is applied to the homogeneous image regions in order to eliminate the noise. It is assumed that the difference between the input image and the thus obtained noiseless version of the image represents the image noise. Finally, the standard deviation of the differences is returned in **Sigma**. It should be noted that this method requires large connected homogeneous image regions to be able to reliably estimate the noise.

Note that the methods *'foerstner'* and *'immerkaer'* assume a Gaussian distribution of the image noise, whereas the methods *'least_squares'* and *'mean'* can be applied to images with arbitrarily distributed noise. In general, the method *'foerstner'* returns the most accurate results while the method *'immerkaer'* shows the fastest computation.

If the image noise could not be estimated reliably, the error 3175 is raised. This may happen if the image does not contain enough homogeneous regions, if the image was artificially created, or if the noise is not of Gaussian type. In order to avoid this error, it might be useful in some cases to try one of the following modifications in dependence of the estimation method that is passed in **Method**:

- Increase the size of the input image domain (useful for all methods).
- Increase the value of the parameter **Percent** (useful for methods *'least_squares'* and *'mean'*).
- Use the method *'immerkaer'*, instead of the methods *'foerstner'*, *'least_squares'*, or *'mean'*. The method *'immerkaer'* does not rely on the existence of homogeneous image regions, and hence is almost always applicable.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter **Filters**.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ object : byte / uint2
Input image.
- ▷ **Method** (input_control) string $\leadsto$ string
Method to estimate the image noise.
- Default:** *'foerstner'*
- List of values:** $\text{Method} \in \{ \text{'foerstner'}, \text{'immerkaer'}, \text{'least_squares'}, \text{'mean'} \}$

- ▷ **Percent** (input_control) number $\leadsto$ real / integer
 Percentage of used image points.
Default: 20
Suggested values: Percent $\in \{1, 2, 5, 7, 10, 15, 20, 30, 40, 50\}$
Restriction: $0 < \text{Percent} \ \&\& \ \text{Percent} \leq 50$.
- ▷ **Sigma** (output_control) real(-array) $\leadsto$ real
 Standard deviation of the image noise.
Assertion: Sigma ≥ 0

Example

```
read_image (Image, 'combine')
estimate_noise (ImageNoise, 'foerstner', 20, SigmaFoerstner)
estimate_noise (ImageNoise, 'immerkaer', 20, SigmaImmerkaer)
estimate_noise (ImageNoise, 'least_squares', 20, SigmaLeastSquares)
estimate_noise (ImageNoise, 'mean', 20, SigmaMean)
```

Result

If the parameters are valid, the operator `estimate_noise` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the image noise could not be estimated reliably, the error 3175 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

```
fit_surface_first_order ( Regions, Image : : Algorithm,
    Iterations, ClippingFactor : Alpha, Beta, Gamma )
```

Calculate gray value moments and approximation by a first order surface (plane).

The operator `fit_surface_first_order` calculates the gray value moments and the parameters of the approximation of the gray values by a first order surface. The calculation is done by minimizing the distance between the gray values and the surface. A first order surface is described by the following formula:

$$\begin{aligned} \text{Image}(r, c) &= \text{Alpha}(r - r_{\text{center}}) \\ &+ \text{Beta}(c - c_{\text{center}}) \\ &+ \text{Gamma} \end{aligned}$$

r_{center} and c_{center} are the center coordinates of intersection of the input region with the full image domain. By the minimization process the parameters from [Alpha](#) to [Gamma](#) is calculated.

The algorithm used for the fitting can be selected via [Algorithm](#):

'regression' Standard 'least squares' line fitting.

'huber' Weighted 'least squares' fitting, where the impact of outliers is decreased based on the approach of Huber.

'tukey' Weighted 'least squares' fitting, where outliers are ignored based on the approach of Tukey.

The parameter [ClippingFactor](#) (a scaling factor for the standard deviation) controls the amount of damping outliers: The smaller the value chosen for [ClippingFactor](#) the more outliers are detected. The detection of outliers is repeated. The parameter [Iterations](#) specifies the number of iterations. If *'regression'* is set for [Algorithm](#) [Iterations](#) is ignored.

Attention

Note that the operator `fit_surface_first_order` only considers the given [Regions](#) and ignores any previously set domain of the input image [Image](#).

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Regions to be checked.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / uint2 / direction / cyclic / real
Corresponding gray values.
- ▷ **Algorithm** (input_control) string $\leadsto$ string
Algorithm for the fitting.
Default: 'regression'
List of values: Algorithm $\in$ {'regression', 'huber', 'tukey'}
- ▷ **Iterations** (input_control) integer $\leadsto$ integer
Maximum number of iterations (unused for 'regression').
Default: 5
Restriction: Iterations ≥ 0
- ▷ **ClippingFactor** (input_control) real $\leadsto$ real
Clipping factor for the elimination of outliers.
Default: 2.0
List of values: ClippingFactor $\in$ {1.0, 1.5, 2.0, 2.5, 3.0}
Restriction: ClippingFactor > 0
- ▷ **Alpha** (output_control) real(-array) $\leadsto$ real
Parameter Alpha of the approximating surface.
- ▷ **Beta** (output_control) real(-array) $\leadsto$ real
Parameter Beta of the approximating surface.
- ▷ **Gamma** (output_control) real(-array) $\leadsto$ real
Parameter Gamma of the approximating surface.

Result

The operator `fit_surface_first_order` returns the value 2 (H_MSG_TRUE) if an image with the defined gray values ('byte') is entered and the parameters are correct. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Possible Successors

[gen_image_surface_first_order](#)

[moments_gray_plane](#), [fit_surface_second_order](#)

Module

Foundation

```
fit_surface_second_order ( Regions, Image : : Algorithm,
    Iterations, ClippingFactor : Alpha, Beta, Gamma, Delta, Epsilon,
    Zeta )
```

Calculate gray value moments and approximation by a second order surface.

The operator `fit_surface_second_order` calculates the gray value moments and the parameters of the approximation of the gray values by a second order surface. The calculation is done by minimizing the distance between the gray values and the surface. A second order surface is described by the following formula:

$$\begin{aligned} \text{Image}(r, c) = & \text{Alpha}(r - r_{center})^2 \\ & + \text{Beta}(c - c_{center})^2 \\ & + \text{Gamma}(r - r_{center}) * (c - c_{center}) \\ & + \text{Delta}(r - r_{center}) \\ & + \text{Epsilon}(c - c_{center}) \\ & + \text{Zeta} \end{aligned}$$

r_{center} and c_{center} are the center coordinates of the intersection of the input region with the full image domain. By the minimization process the parameters from `Alpha` to `Zeta` is calculated.

The algorithm used for the fitting can be selected via `Algorithm`:

'regression' Standard 'least squares' fitting.

'huber' Weighted 'least squares' fitting, where the impact of outliers is decreased based on the approach of Huber.

'tukey' Weighted 'least squares' fitting, where outliers are ignored based on the approach of Tukey.

The parameter `ClippingFactor` (a scaling factor for the standard deviation) controls the amount of damping outliers: The smaller the value chosen for `ClippingFactor` the more outliers are detected. The detection of outliers is repeated. The parameter `Iterations` specifies the number of iterations. If 'regression' is set for `Algorithm` `Iterations` is ignored.

Attention

Note that the operator `fit_surface_second_order` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Regions to be checked.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / uint2 / direction / cyclic / real
Corresponding gray values.
- ▷ **Algorithm** (input_control) string $\leadsto$ string
Algorithm for the fitting.
Default: 'regression'
List of values: Algorithm $\in$ {'regression', 'tukey', 'huber'}
- ▷ **Iterations** (input_control) integer $\leadsto$ integer
Maximum number of iterations (unused for 'regression').
Default: 5
Restriction: Iterations ≥ 0
- ▷ **ClippingFactor** (input_control) real $\leadsto$ real
Clipping factor for the elimination of outliers.
Default: 2.0
List of values: ClippingFactor $\in$ {1.0, 1.5, 2.0, 2.5, 3.0}
Restriction: ClippingFactor > 0
- ▷ **Alpha** (output_control) real(-array) $\leadsto$ real
Parameter Alpha of the approximating surface.
- ▷ **Beta** (output_control) real(-array) $\leadsto$ real
Parameter Beta of the approximating surface.

- ▷ **Gamma** (output_control) real(-array) $\rightsquigarrow$ real
Parameter Gamma of the approximating surface.
- ▷ **Delta** (output_control) real(-array) $\rightsquigarrow$ real
Parameter Delta of the approximating surface.
- ▷ **Epsilon** (output_control) real(-array) $\rightsquigarrow$ real
Parameter Epsilon of the approximating surface.
- ▷ **Zeta** (output_control) real(-array) $\rightsquigarrow$ real
Parameter Zeta of the approximating surface.

Result

The operator `fit_surface_second_order` returns the value 2 (H_MSG_TRUE) if an image with the defined gray values ('byte') is entered and the parameters are correct. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Module

Foundation

fuzzy_entropy (Regions, Image : : Apar, Cpar : Entropy)

Determine the fuzzy entropy of regions.

`fuzzy_entropy` calculates the fuzzy entropy of a fuzzy set. To do so, the image is regarded as a fuzzy set. The entropy then is a measure of how well the image approximates a white or black image. It is defined as follows:

$$H(X) = \frac{1}{MN \ln 2} \sum_l T_e(l) h(l)$$

where $M \times N$ is the size of the image, and $h(l)$ is the histogram of the image. Furthermore,

$$T_e(l) = -\mu(l) \ln \mu(l) - (1 - \mu(l)) \ln(1 - \mu(l))$$

Here, $u(x(m, n))$ is a fuzzy membership function defining the fuzzy set (see [fuzzy_perimeter](#)). The same restrictions hold as in [fuzzy_perimeter](#).

Attention

Note that for `fuzzy_entropy`, the [Regions](#) must lie completely within the previously defined domain. Otherwise an exception is raised.

Parameters

- ▷ **Regions** (input_object) region(-array) $\rightsquigarrow$ object
Regions for which the fuzzy entropy is to be calculated.
- ▷ **Image** (input_object) singlechannelimage $\rightsquigarrow$ object : byte
Input image containing the fuzzy membership values.
- ▷ **Apar** (input_control) integer $\rightsquigarrow$ integer
Start of the fuzzy function.

Default: 0

Suggested values: Apar $\in$ {0, 5, 10, 20, 50, 100}

Value range: $0 \leq \text{Apar} \leq 255$ (lin)

Minimum increment: 1

Recommended increment: 5

- ▷ **Cpar** (input_control) integer $\leadsto$ integer
 End of the fuzzy function.
Default: 255
Suggested values: Cpar $\in$ {50, 100, 150, 200, 220, 255}
Value range: $0 \leq \text{Cpar} \leq 255$ (lin)
Minimum increment: 1
Recommended increment: 5
Restriction: Apar $\leq$ Cpar
- ▷ **Entropy** (output_control) real(-array) $\leadsto$ real
 Fuzzy entropy of a region.

Example

```
* To find a Fuzzy Entropy from an Image
read_image(Image, 'monkey')
fuzzy_entropy(Trans, Trans, 0, 255, Entro)
```

Result

The operator `fuzzy_entropy` returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

fuzzy_perimeter (Regions, Image : : Apar, Cpar : Perimeter)
--

Calculate the fuzzy perimeter of a region.

The operator `fuzzy_perimeter` is used to determine the differences of fuzzy membership between an image point and its neighbor points. The right and lower neighbor are taken into account. The fuzzy perimeter is then defined as follows:

$$p(X) = \sum_{m=1}^{M-1} \sum_{n=1}^{N-1} |\mu_X(x_{m,n}) - \mu_X(x_{m,n+1})| + \sum_{m=1}^{M-1} \sum_{n=1}^{N-1} |\mu_X(x_{m,n}) - \mu_X(x_{m+1,n})|$$

where $M \times N$ is the size of the image, and $\mu(x(m,n))$ is the fuzzy membership function (i.e., the input image). This implementation uses Zadeh's Standard-S function, which is defined as follows:

$$\mu_X(x) = \begin{cases} 0, & x \leq a \\ 2 \left(\frac{x-a}{c-a} \right)^2, & a < x \leq b \\ 1 - 2 \left(\frac{x-a}{c-a} \right)^2, & b < x \leq c \\ 1, & c \leq x \end{cases}$$

The parameters a , b and c obey the following restrictions: $b = \frac{a+c}{2}$ is the inflection point of the function, $\Delta b = b - a = c - b$ is the bandwidth, and for $x = b$ $\mu(x) = 0.5$ holds. In `fuzzy_perimeter`, the parameters `Apar` and `Cpar` are defined as follows: b is $\frac{Apar+Cpar}{2}$.

Attention

Note that for `fuzzy_perimeter`, the `Regions` must lie completely within the previously defined domain. Otherwise an exception is raised.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Regions for which the fuzzy perimeter is to be calculated.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte
Input image containing the fuzzy membership values.
- ▷ **Apar** (input_control) integer $\leadsto$ integer
Start of the fuzzy function.
Default: 0
Suggested values: `Apar` $\in$ {0, 5, 10, 20, 50, 100}
Value range: $0 \leq Apar \leq 255$ (lin)
Minimum increment: 1
Recommended increment: 5
- ▷ **Cpar** (input_control) integer $\leadsto$ integer
End of the fuzzy function.
Default: 255
Suggested values: `Cpar` $\in$ {50, 100, 150, 200, 220, 255}
Value range: $0 \leq Cpar \leq 255$ (lin)
Minimum increment: 1
Recommended increment: 5
Restriction: `Apar` $\leq$ `Cpar`
- ▷ **Perimeter** (output_control) real(-array) $\leadsto$ real
Fuzzy perimeter of a region.

Example

```
* To find a Fuzzy Entropy from an Image
read_image(Image, 'monkey')
fuzzy_perimeter(Trans, Trans, 0, 255, Per)
```

Result

The operator `fuzzy_perimeter` returns the value 2 (`H_MSG_TRUE`) if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

gen_cooc_matrix (Regions, Image : Matrix : LdGray, Direction :)

Calculate the co-occurrence matrix of a region in an image.

The operator `gen_cooc_matrix` determines from the input regions how often the gray values i and j are located next to each other in a certain direction (0, 45, 90, 135 degrees), stores this number in the co-occurrence matrix at the locations (i, j) and (j, i) (the matrix is symmetrical), and finally scales the matrix with the number of entries. `LdGray` indicates the number of gray values to be distinguished (namely 2^{LdGray}).

Example: Input image with gray values (scaled with `LdGray=2`)

0	0	3
1	1	2
1	2	3

Co-occurrence matrix (not scaled):

	0	1	2	3
0:	2	0	0	1
135:	0	2	2	0
90:	0	2	0	1
45:	1	0	1	1
	1	1	0	0
	0	1	0	0

Attention

Note that the operator `gen_cooc_matrix` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Region to be checked.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte
Image providing the gray values.
- ▷ **Matrix** (output_object) image(-array) $\leadsto$ object : real
Co-occurrence matrix (matrices).
- ▷ **LdGray** (input_control) integer $\leadsto$ integer
Number of gray values to be distinguished (2^{LdGray}).
Default: 6
List of values: `LdGray` $\in$ {1, 2, 3, 4, 5, 6, 7, 8}
(lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Direction** (input_control) integer $\leadsto$ integer
Direction of neighbor relation.
Default: 0
List of values: `Direction` $\in$ {0, 45, 90, 135}

Result

The operator `gen_cooc_matrix` returns the value 2 (`H_MSG_TRUE`) if an image with defined gray values is entered and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result', <Result>:)`, the behavior in case of empty region is set via `set_system(::'empty_region_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

gray_features (Regions, Image : : Features : Value)
--

Calculates gray value features for a set of regions.

gray_features has a set of regions ([Regions](#)) as input. For each of these regions the features ([Features](#)) are calculated and returned in [Value](#).

Possible values for [Features](#):

- 'area': Gray value volume of region (see [area_center_gray](#))
- 'row': Row index of the center of gravity (see [area_center_gray](#))
- 'column': Column index of the center of gravity (see [area_center_gray](#))
- 'ra': Major axis of equivalent ellipse (see [elliptic_axis_gray](#))
- 'rb': Minor axis of equivalent ellipse (see [elliptic_axis_gray](#))
- 'phi': Orientation of equivalent ellipse (see [elliptic_axis_gray](#))
- 'min': Minimum gray value (see [min_max_gray](#))
- 'max': Maximum gray value (see [min_max_gray](#))
- 'median': Median gray value (see [min_max_gray](#), with Percent=50)
- 'mean': Mean gray value (see [intensity](#))
- 'deviation': Deviation of gray values (see [intensity](#))
- 'plane_deviation': Deviation from the approximating plane (see [plane_deviation](#))
- 'anisotropy': Anisotropy (see [entropy_gray](#))
- 'entropy': Entropy (see [entropy_gray](#))
- 'fuzzy_entropy': Fuzzy entropy of region (see [fuzzy_entropy](#), with a fuzzy function from A_{par}=0 to C_{par}=255)
- 'fuzzy_perimeter': Fuzzy perimeter of region (see [fuzzy_perimeter](#), with a fuzzy function from A_{par}=0 to C_{par}=255)
- 'moments_row': Mixed moments along a row (see [moments_gray_plane](#))
- 'moments_column': Mixed moments along a column (see [moments_gray_plane](#))
- 'alpha': Approximating plane, parameter Alpha (see [moments_gray_plane](#))
- 'beta': Approximating plane, parameter Beta (see [moments_gray_plane](#))

Attention

Several features are processed in the order in which they are entered.

Note that the operator gray_features only considers the given [Regions](#) and ignores any previously set domain of the input image [Image](#).

Parameters

- ▷ **Regions** (input_object) region-array $\leadsto$ object
Regions to be examined.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Gray value image.
- ▷ **Features** (input_control) string(-array) $\leadsto$ string
Names of the features.
Default: 'mean'
List of values: Features $\in$ {'area', 'row', 'column', 'ra', 'rb', 'phi', 'min', 'max', 'median', 'mean', 'deviation', 'plane_deviation', 'anisotropy', 'entropy', 'fuzzy_entropy', 'fuzzy_perimeter', 'moments_row', 'moments_column', 'alpha', 'beta'}
- ▷ **Value** (output_control) real(-array) $\leadsto$ real
Values of the features.

Complexity

If F is the area of the region and N the number of features the runtime complexity is $O(F * N)$.

Result

The operator `gray_features` returns the value 2 (`H_MSG_TRUE`) if the input image has the defined gray values and the parameters are correct. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

gray_histo (<code>Regions</code> , <code>Image</code> : : : <code>AbsoluteHisto</code> , <code>RelativeHisto</code>)

Calculate the gray value distribution.

The operator `gray_histo` calculates for the image (`Image`) within `Regions` the absolute (`AbsoluteHisto`) and relative (`RelativeHisto`) histogram of the gray values.

Both histograms are tuples of 256 values, which — beginning at 0 — contain the frequencies of the individual gray values of the image.

`AbsoluteHisto` indicates the absolute frequencies of the gray values in integers, and `RelativeHisto` indicates the relative, i.e. the absolute frequencies divided by the area of the image as floating point numbers.

'real'-, 'int2'-, 'uint2'-, and 'int4'-images are transformed into 'byte'-images (first the largest and smallest gray value in the image are determined, and then the original gray values are mapped linearly into the area 0..255) and then processed as mentioned above.

Attention

Note that the operator `gray_histo` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

Real, int2, uint2, and int4 images are reduced to 256 gray values.

`gray_histo` can be executed on OpenCL devices for byte, int1, directional and cyclic images if the OpenCL device supports the `cl_khr_local_int32_base_atomics` and `cl_khr_global_int32_base_atomics` extensions (which are optional in OpenCL 1.0). Unlike most other HALCON operators, `gray_histo` can be substantially slower on an OpenCL device if the `Image` is not completely included in the `Regions`.

OpenCL support is not available in HALCON XL, as 64 bit atomic integer arithmetic would be required.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Region in which the histogram is to be calculated.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / cyclic / direction / int1 / int2 / uint2 / int4 / real
Image the gray value distribution of which is to be calculated.
- ▷ **AbsoluteHisto** (output_control) histogram-array $\leadsto$ integer
Absolute frequencies of the gray values.

▷ **RelativeHisto** (output_control) histogram-array $\leadsto$ real
Frequencies, normalized to the area of the region.

Complexity

If F is the area of the region the runtime complexity is $O(F + 255)$.

Result

The operator `gray_histo` returns the value 2 (`H_MSG_TRUE`) if the image has defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(:,:, 'no_object_result', <Result>:)`, the behavior in case of empty region is set via `set_system(:,:, 'empty_region_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Successors

`histo_to_thresh`, `gen_region_histo`

Alternatives

`set_paint`, `histo_2dim`, `scale_image_max`, `entropy_gray`

Module

Foundation

gray_histo_abs (Regions, Image : : Quantization : AbsoluteHisto)

Calculate the gray value distribution.

The operator `gray_histo_abs` calculates for the image (`Image`) within `Regions` the absolute (`AbsoluteHisto`) histogram of the gray values.

The parameter `Quantization` defines, how many frequencies of neighbored gray values are added for one frequency value. The resulting histogram `AbsoluteHisto` is a tuple, whose indices are mapped on the gray values of the input image `Image` and whose elements contain the frequencies of the gray values. The indices i of the frequency value are calculated from the gray values g and the quantization q as follows:

- For unsigned image types:

$$i = \left\lceil \frac{g + 0.5}{q} \right\rceil$$

- For signed image types:

$$i = \left\lceil \frac{g - (MIN - 0.5)}{q} \right\rceil$$

whereas `MIN` denotes the minimal gray value, e.g., -128 for an `int1` image type. Therefore, the size of the tuple results from the ratio of the full domain of gray values and the quantization, e.g., for images of `int2` in $\lceil \frac{65536}{3.0} \rceil = 21846$. The origin gray value of the signed image types `int1` resp. `int2` is mapped on the index 128 resp. 32768, negative resp. positive gray values have smaller resp. greater indices.

Attention

Note that the operator `gray_histo_abs` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Region in which the histogram is to be calculated.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / cyclic / direction / int1 / int2 / uint2
Image the gray value distribution of which is to be calculated.
- ▷ **Quantization** (input_control) number $\leadsto$ real / integer
Quantization of the gray values.
Default: 1.0
Suggested values: Quantization $\in$ {1.0, 2.0, 3.0, 5.0, 10.0}
Restriction: Quantization $\geq$ 1.0
- ▷ **AbsoluteHisto** (output_control) histogram-array $\leadsto$ integer
Absolute frequencies of the gray values.

Result

The operator `gray_histo_abs` returns the value 2 (`H_MSG_TRUE`) if the image has defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(, 'no_object_result', <Result>:)`, the behavior in case of empty region is set via `set_system(, 'empty_region_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Successors

`histo_to_thresh`, `gen_region_histo`

Module

Foundation

gray_histo_range (Regions, Image : : Min, Max, NumBins : Histo, BinSize)

Calculate the gray value distribution of a single channel image within a certain gray value range.

`gray_histo_range` calculates the gray value distribution `Histo` of the single channel `Image` within `Regions` and the gray value range `[Min,Max]`. The values for `Min` and `Max` are rounded down to the next integer if the `Image` is not of type 'real'. The gray value range is divided into `NumBins` bins of the same size, which is returned in `BinSize`. If a gray value lies between two bins the gray value is assigned to the smaller bin. If the `Image` is of type 'real' $\text{BinSize} = \frac{\text{Max}-\text{Min}}{\text{NumBins}}$. If the `Image` has discrete gray values the size of a bin is computed with $\text{BinSize} = \frac{\text{Max}-\text{Min}+1}{\text{NumBins}}$. Since the accuracy of the histogram `Histo` can be adjusted with `NumBins`, the calculation of the gray value histogram with `gray_histo_range` is most useful for images of type 'real' and images of type 'integer', which have a high bit depth.

Attention

Note that the operator `gray_histo_range` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

If the `Image` has discrete gray values the value of `BinSize` may cause the following effects: For `BinSize > 1` multiple neighboring gray values are assigned to the same bin. If `BinSize` is no integer the gray values are distributed uneven among the bins, e.g., for `BinSize = 1.5` the first and second gray value are assigned to the first bin, the third gray value is assigned to the second bin, and the fourth and fifth gray value are assigned to the third bin. This becomes noticeable in several peaks in the histogram `Histo`. If `BinSize < 1` some classes are not assigned by any gray value, e.g., for `BinSize = 0.5` the first gray value is assigned to the first bin and the second

gray value is assigned to the third bin. The histogram `Histo` shows some gaps, which resembles the structure of a comb.

If the `Image` is of type 'real' and `Min = Max`, all pixels of the corresponding gray value are assigned only to the first bin.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Region in which the histogram is to be calculated.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / cyclic / direction / int1 / uint2 / int2 / int4 / int8 / real
Input image.
- ▷ **Min** (input_control) real $\leadsto$ real / integer
Minimum gray value.
Default: 0
Suggested values: Min $\in$ {0}
- ▷ **Max** (input_control) real $\leadsto$ real / integer
Maximum gray value.
Default: 255
Suggested values: Max $\in$ {255}
Restriction: Max $\geq$ Min
- ▷ **NumBins** (input_control) integer $\leadsto$ integer
Number of bins.
Default: 256
Suggested values: NumBins $\in$ {16, 32, 64, 128, 256}
Restriction: NumBins $\geq$ 1
- ▷ **Histo** (output_control) histogram(-array) $\leadsto$ integer
Histogram to be calculated.
- ▷ **BinSize** (output_control) real $\leadsto$ real
Bin size.

Result

If the parameters are valid, the operator `gray_histo_range` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Foundation

```
gray_projections ( Region, Image : : Mode : HorProjection,
                   VertProjection )
```

Calculate horizontal and vertical gray-value projections.

`gray_projections` calculates the horizontal and vertical gray-value projections, i.e., the mean values in the horizontal and vertical direction of the gray values of the input image `Image` within the input region `Region`.

If `Mode` = 'simple' is selected the projection is performed in the direction of the coordinate axes of the image, i.e.:

$$\begin{aligned}\text{HorProjection}(r) &= \frac{1}{n(r+r')} \sum_{(r+r', c+c') \in \text{Region}} \text{Image}(r+r', c+c') \\ \text{VertProjection}(c) &= \frac{1}{n(c+c')} \sum_{(r+r', c+c') \in \text{Region}} \text{Image}(r+r', c+c')\end{aligned}$$

Here, (r', c') denotes the upper left corner of the smallest enclosing axis-parallel rectangle of the input region (see `smallest_rectangle1`), and $n(x)$ denotes the number of region points in the corresponding row $r+r'$ or column $c+c'$. Hence, the horizontal projection returns a one-dimensional function that reflects the vertical gray value changes. Likewise, the vertical projection returns a function that reflects the horizontal gray value changes.

If `Mode` = 'rectangle' is selected the projection is performed in the direction of the major axes of the smallest enclosing rectangle of arbitrary orientation of the input region (see `smallest_rectangle2`). Here, the horizontal projection direction corresponds to the larger axis, while the vertical direction corresponds to the smaller axis. In this mode, all gray values within the smallest enclosing rectangle of arbitrary orientation of the input region are used to compute the projections.

Attention

The operator `gray_projections` only considers the given `Region` and ignores any previously set domain of the input image `Image`.

If $n(x) = 0$, i.e., if there are no region points in the corresponding row $r+r'$ or column $c+c'$, the respective value of `HorProjection` or `VertProjection` is set to -1 .

`gray_projections` can be executed on an OpenCL device for the 'simple' mode if the OpenCL device supports the `cl_khr_global_int32_base_atomics` OpenCL extension. For processing images of type real, the OpenCL device must support the `cl_khr_fp64` and `cl_khr_int64_base_atomics` extensions.

Parameters

- ▷ **Region** (input_object) region $\leadsto$ object
Region to be processed.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / int2 / uint2 / real
Grayvalues for projections.
- ▷ **Mode** (input_control) string $\leadsto$ string
Method to compute the projections.
Default: 'simple'
List of values: Mode $\in$ {'simple', 'rectangle'}
- ▷ **HorProjection** (output_control) real-array $\leadsto$ real
Horizontal projection.
- ▷ **VertProjection** (output_control) real-array $\leadsto$ real
Vertical projection.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

1D Metrology

histo_2dim (Regions, ImageCol, ImageRow : Histo2Dim : :)

Calculate the histogram of two-channel gray value images.

The operator `histo_2dim` calculates the 2-dimensional histogram of two images within [Regions](#). The gray values of channel 1 ([ImageCol](#)) are interpreted as row index, those of channel 2 ([ImageRow](#)) as column index. The gray value at one point $P(g1, g2)$ in the output image [Histo2Dim](#) indicates the frequency of the gray value combination $(g1, g2)$ with $g1$ indicating the line index and $g2$ the column index.

Attention

Note that the operator `histo_2dim` only considers the given [Regions](#) and ignores any previously set domain of the input images.

Parameters

- ▷ **Regions** (input_object) `region(-array)` $\leadsto$ *object*
Region in which the histogram is to be calculated.
- ▷ **ImageCol** (input_object) `(multichannel-)image` $\leadsto$ *object* : `byte / direction / cyclic / int1`
Channel 1.
- ▷ **ImageRow** (input_object) `(multichannel-)image` $\leadsto$ *object* : `byte / direction / cyclic / int1`
Channel 2.
- ▷ **Histo2Dim** (output_object) `image` $\leadsto$ *object* : `int4`
Histogram to be calculated.

Example

```
read_image (Image, 'monkey')
get_domain (Image, Domain)
gauss_filter (Image, ImageGauss, 7)
histo_2dim (Domain, ImageGauss, Image, Histo2Dim)
dev_display (Histo2Dim)
```

Complexity

If F is the plane of the region, the runtime complexity is $O(F + 256^2)$.

Result

The operator `histo_2dim` returns the value 2 (`H_MSG_TRUE`) if both images have defined gray values. The behavior in case of empty input (no input images available) is set via the operator `set_system (:: 'no_object_result', <Result>:)`, the behavior in case of empty region is set via `set_system (:: 'empty_region_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

[get_grayval](#)

Module

Foundation

intensity ([Regions](#), [Image](#) : : : [Mean](#), [Deviation](#))

Calculate the mean and deviation of gray values.

The operator `intensity` calculates the mean and the deviation of the gray values in the input image within `Regions`. If R is a region, p a pixel from R with the gray value $g(p)$ and F the plane ($F = |R|$), the features are defined by:

$$\text{Mean} = \frac{\sum_{p \in R} g(p)}{F}$$

$$\text{Deviation} = \sqrt{\frac{\sum_{p \in R} (g(p) - \text{Mean})^2}{F}}$$

Attention

Note that the operator `intensity` only considers the given `Regions` and ignores any previously set domain of the input image `Image`. The calculation of `Deviation` does not follow the usual definition if the region of the image contains only one pixel. In this case 0.0 is returned.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Regions in which the features are calculated.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Gray value image.
- ▷ **Mean** (output_control) real(-array) $\leadsto$ real
Mean gray value of a region.
- ▷ **Deviation** (output_control) real(-array) $\leadsto$ real
Deviation of gray values within a region.

Complexity

If F is the area of the region, the runtime complexity is $O(F)$.

Result

The operator `intensity` returns the value 2 (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result', <Result>:)`, the behavior in case of empty region is set via `set_system(::'empty_region_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

`threshold`

Alternatives

`select_gray`, `min_max_gray`

`mean_image`, `gray_histo`, `gray_histo_abs`

Module

Foundation

min_max_gray (Regions, Image : : Percent : Min, Max, Range)

Determine the minimum and maximum gray values within regions.

The operator `min_max_gray` creates the histogram of the absolute frequencies of the gray values within `Regions` in the input image `Image` (see `gray_histo`) and calculates the number of pixels `Percent` corresponding to the area of the input image. Then it goes inwards on both sides of the histogram by this number of pixels and determines the smallest and the largest gray value:

Example:

With area = 60, Percent = 5, d.h. i.e. 3 pixels, histogram = [2,8,0,7,13,0,0,...,0,10,10,5,3,1,1],
 $\Rightarrow$ Minimum = 0, Maximum = 255, range = 255
 min_max_gray returns: Min = 1, Max = 253, Range = 252.

For images of type int4, int8, and real, the above calculation is not performed via histograms, but using a rank selection algorithm. If Percent is set to 50, Min = Max = Median. If Percent is 0 no histogram is calculated in order to enhance the runtime.

Attention

Note that the operator min_max_gray only considers the given Regions and ignores any previously set domain of the input image Image.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Regions, the features of which are to be calculated.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Gray value image.
- ▷ **Percent** (input_control) number $\leadsto$ real / integer
Percentage below (above) the absolute maximum (minimum).
Default: 0
Suggested values: Percent $\in \{0, 1, 2, 5, 7, 10, 15, 20, 30, 40, 50\}$
Restriction: 0 <= Percent && Percent <= 50
- ▷ **Min** (output_control) real(-array) $\leadsto$ real
"Minimum" gray value.
- ▷ **Max** (output_control) real(-array) $\leadsto$ real
"Maximum" gray value.
Assertion: Max >= Min
- ▷ **Range** (output_control) real(-array) $\leadsto$ real
Difference between Max and Min.
Assertion: Range >= 0

Example

```
* Threshold segmentation with training region:
read_image(Image, 'fabrik')
draw_region(Region, WindowHandle)
min_max_gray(Region, Image, 5, Min, Max, Range)
threshold(Image, SegmentedRegion, Min, Max)
dev_display(SegmentedRegion)
```

Result

The operator min_max_gray returns the value 2 (H_MSG_TRUE) if the input image has the defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator set_system(:,:, 'no_object_result', <Result>:). The behavior in case of an empty region is set via the operator set_system(:,:, 'empty_region_result', <Result>:). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

draw_region, gen_circle, gen_ellipse, gen_rectangle1, threshold, regiongrowing

Possible Successors

threshold

Alternatives

`gray_histo, scale_image, scale_image_max, learn_ndim_norm`

Module

Foundation

moments_gray_plane (*Regions*, *Image* : : : *MRow*, *MCol*, *Alpha*,
Beta, *Mean*)

Calculate gray value moments and approximation by a plane.

The operator `moments_gray_plane` calculates the gray value moments and the parameters of the approximation of the gray values by a plane. The calculation is carried out according to the following formula:

$$\begin{aligned}
 \text{MRow} &= \frac{1}{F^2} \sum_{(r,c) \in \text{Regions}} (r - \bar{r})(\text{Image}(r, c) - \text{Mean}) \\
 \text{MCol} &= \frac{1}{F^2} \sum_{(r,c) \in \text{Regions}} (c - \bar{c})(\text{Image}(r, c) - \text{Mean}) \\
 \text{Alpha} &= \frac{\text{MRow} F m_{02} - m_{11} \text{MCol}}{F} m_{20} m_{02} - m_{11}^2 \\
 \text{Beta} &= \frac{m_{20} \text{MCol} F - \text{MRow} F m_{11}}{m_{20} m_{02} - m_{11}^2}
 \end{aligned}$$

where F is the plane, $\bar{r}$, $\bar{c}$ the center, and m_{11} , m_{20} , and m_{02} the scaled moments of `Regions`.

The parameters `Alpha`, `Beta` and `Mean` describe a plane above the region:

$$\text{Image}'(r, c) = \text{Alpha}(r - \bar{r}) + \text{Beta}(c - \bar{c}) + \text{Mean}$$

Thus `Alpha` indicates the gradient in the direction of the line axis (“down”), `Beta` the gradient in the direction of the column axis (to the “right”).

Attention

Note that the operator `moments_gray_plane` only considers the given `Regions` and ignores any previously set domain of the input image `Image`.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Regions to be checked.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / direction / cyclic / uint2 / real
Corresponding gray values.
- ▷ **MRow** (output_control) real(-array) $\leadsto$ real
Mixed moments along a line.
- ▷ **MCol** (output_control) real(-array) $\leadsto$ real
Mixed moments along a column.
- ▷ **Alpha** (output_control) real(-array) $\leadsto$ real
Parameter Alpha of the approximating plane.
- ▷ **Beta** (output_control) real(-array) $\leadsto$ real
Parameter Beta of the approximating plane.
- ▷ **Mean** (output_control) real(-array) $\leadsto$ real
Mean gray value.

Result

The operator `moments_gray_plane` returns the value 2 (`H_MSG_TRUE`) if an image with the defined gray values (`'byte'`) is entered and the parameters are correct. The behavior in case of empty input (no input images

available) is set via the operator `set_system(:,:, 'no_object_result', <Result>:)`, the behavior in case of empty region is set via `set_system(:,:, 'empty_region_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

plane_deviation (Regions, Image : : : Deviation)

Calculate the deviation of the gray values from the approximating image plane.

The operator `plane_deviation` calculates the deviation of the gray values in `Image` from the approximation of the gray values through a plane. Contrary to the standard deviation in case of `intensity` slanted gray value planes also receive the value zero. The gray value plane is calculated according to `gen_image_gray_ramp`. If F is the area of the region, α , β , and μ the parameters of the image plane, and (r', c') the center of the region, `Deviation` is defined by:

$$\text{Deviation} = \sqrt{\frac{\sum_{(r,c) \in \text{Regions}} ((\alpha(r - r') + \beta(c - c') + \mu) - \text{Image}(r, c))^2}{F}}$$

Attention

Note that the operator `plane_deviation` only considers the given `Regions` and ignores any previously set domain of the input image `Image`. It should be noted that the calculation of `Deviation` does not follow the usual definition. It is defined to return the value 0.0 for an image with only one pixel.

Parameters

- ▷ **Regions** (input_object) region(-array) $\leadsto$ object
Regions, of which the plane deviation is to be calculated.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / cyclic
Gray value image.
- ▷ **Deviation** (output_control) real(-array) $\leadsto$ real
Deviation of the gray values within a region.

Complexity

If F is the area of the region the runtime complexity amounts to $O(F)$.

Result

The operator `plane_deviation` returns the value 2 (`H_MSG_TRUE`) if `Image` is of the type 'byte'. The behavior in case of empty input (no input images available) is set via the operator `set_system(:,:, 'no_object_result', <Result>:)`, the behavior in case of empty region is set via `set_system(:,:, 'empty_region_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

[moments_gray_plane](#)

Module

Foundation

```
select_gray ( Regions, Image : SelectedRegions : Features,
              Operation, Min, Max : )
```

Select regions based on gray value features.

The operator `select_gray` has a number of regions ([Regions](#)) as input. For each of these regions the ([Features](#)) are calculated. The region is transferred (duplicated) into the output [SelectedRegions](#), if each ([Operation](#) = 'and') or at least one ([Operation](#) = 'or') of the calculated features is within the limits. The limits are defined by the parameters [Min](#) and [Max](#). Thereby, [Min](#) and [Max](#) can also be set to 'min' or 'max', respectively, corresponding to setting the smallest or largest value possible for this feature. The parameter [Image](#) contains an image which returns the gray values for calculating the features.

Restriction:

$$\text{Min}_i \leq \text{Features}_i(\text{Regions}, \text{Image}) \leq \text{Max}_i$$

Possible values for [Features](#):

- 'area': Gray value volume of region (see [area_center_gray](#))
- 'row': Row index of the center of gravity (see [area_center_gray](#))
- 'column': Column index of the center of gravity (see [area_center_gray](#))
- 'ra': Major axis of equivalent ellipse (see [elliptic_axis_gray](#))
- 'rb': Minor axis of equivalent ellipse (see [elliptic_axis_gray](#))
- 'phi': Orientation of equivalent ellipse (see [elliptic_axis_gray](#))
- 'min': Minimum gray value (see [min_max_gray](#))
- 'max': Maximum gray value (see [min_max_gray](#))
- 'median': Median gray value (see [min_max_gray](#), with `Percent=50`)
- 'mean': Mean gray value (see [intensity](#))
- 'deviation': Deviation of gray values (see [intensity](#))
- 'plane_deviation': Deviation from the approximating plane (see [plane_deviation](#))
- 'anisotropy': Anisotropy (see [entropy_gray](#))
- 'entropy': Entropy (see [entropy_gray](#))
- 'fuzzy_entropy': Fuzzy entropy of region (see [fuzzy_entropy](#), with a fuzzy function from `Apar=0` to `Cpar=255`)
- 'fuzzy_perimeter': Fuzzy perimeter of region (see [fuzzy_perimeter](#), with a fuzzy function from `Apar=0` to `Cpar=255`)
- 'moments_row': Mixed moments along a row (see [moments_gray_plane](#))
- 'moments_column': Mixed moments along a column (see [moments_gray_plane](#))
- 'alpha': Approximating plane, parameter Alpha (see [moments_gray_plane](#))
- 'beta': Approximating plane, parameter Beta (see [moments_gray_plane](#))

Attention

Note that the operator `select_gray` only considers the given [Regions](#) and ignores any previously set domain of the input image [Image](#). If only one feature is used the value of [Operation](#) is meaningless. Several features are processed in the order in which they are entered. The maximum number of features is limited to 100.

Parameters

- ▷ **Regions** (input_object) region-array $\leadsto$ object
Regions to be examined.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Gray value image.
- ▷ **SelectedRegions** (output_object) region-array $\leadsto$ object
Regions having features within the limits.
- ▷ **Features** (input_control) string(-array) $\leadsto$ string
Names of the features.
Default: 'mean'
List of values: Features $\in$ {'area', 'row', 'column', 'ra', 'rb', 'phi', 'min', 'max', 'median', 'mean', 'deviation', 'plane_deviation', 'anisotropy', 'entropy', 'fuzzy_entropy', 'fuzzy_perimeter', 'moments_row', 'moments_column', 'alpha', 'beta'}
- ▷ **Operation** (input_control) string $\leadsto$ string
Logical connection of features.
Default: 'and'
List of values: Operation $\in$ {'and', 'or'}
- ▷ **Min** (input_control) number(-array) $\leadsto$ real / integer / string
Lower limit(s) of features or 'min'.
Default: 128.0
Suggested values: Min $\in$ {0.5, 1.0, 10.0, 20.0, 50.0, 128.0, 255.0, 1000.0, 'min'}
- ▷ **Max** (input_control) number(-array) $\leadsto$ real / integer / string
Upper limit(s) of features or 'max'.
Default: 255.0
Suggested values: Max $\in$ {0.5, 1.0, 10.0, 20.0, 50.0, 128.0, 255.0, 1000.0, 'max'}

Complexity

If F is the area of the region and N the number of features the runtime complexity is $O(F * N)$.

Result

The operator `select_gray` returns the value 2 (`H_MSG_TRUE`) if the input image has the defined gray values and the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(:,:, 'no_object_result', <Result>:)`, the behavior in case of empty region is set via `set_system(:,:, 'empty_region_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Module

Foundation

```
shape_histo_all ( Region, Image : : Feature : AbsoluteHisto,
                  RelativeHisto )
```

Determine a histogram of features along all threshold values.

The operator `shape_histo_all` carries out 255 threshold operations within `Region` with the gray values of `Image`. The entry i in the histogram corresponds to the number of connected components/holes of this image segmented with the threshold i (`Feature = 'connected_components', 'holes'`) or the mean value of the feature values of the regions segmented in this way (`Feature = 'convexity', 'compactness', 'anisometry'`), respectively.

Attention

The operator `shape_histo_all` expects a region and exactly one gray value image as input. Because of the power of this operator the runtime of `shape_histo_all` is relatively large!

Note that the operator `shape_histo_all` only considers the given `Region` and ignores any previously set domain of the input image `Image`.

Parameters

- ▷ **Region** (input_object) region $\leadsto$ object
Region in which the features are to be examined.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte
Gray value image.
- ▷ **Feature** (input_control) string $\leadsto$ string
Feature to be examined.
Default: 'connected_components'
List of values: Feature $\in$ {'connected_components', 'convexity', 'compactness', 'anisometry', 'holes'}
- ▷ **AbsoluteHisto** (output_control) histogram-array $\leadsto$ real / integer
Absolute distribution of the feature.
- ▷ **RelativeHisto** (output_control) histogram-array $\leadsto$ real
Relative distribution of the feature.

Example

```
* Simulation of shape_histo_all with feature 'connected_components':
* my_shape_histo_all (Region, Image, AbsHisto, RelHisto) :
reduce_domain (Region, Image, RegionGray)
for i := 0 to 255 by 1
    threshold (RegionGray, Seg, i, 255)
    connect_and_holes (Seg, NumConnected, _)
    AbsHisto[i] := NumConnected
endfor
Sum := 0
for i := 0 to 255 by 1
    Sum := Sum + AbsHisto[i]
endfor
for i := 0 to 255 by 1
    RelHisto[i] := AbsHisto[i] / Sum
endfor
```

Complexity

If F is the area of the input region and N the mean number of connected components the runtime complexity is $O(255(F + \sqrt{F}\sqrt{N}))$.

Result

The operator `shape_histo_all` returns the value 2 (`H_MSG_TRUE`) if an image with the defined gray values is entered. The behavior in case of empty input (no input images) is set via the operator `set_system(, 'no_object_result', <Result>:)`, the behavior in case of empty region is set via `set_system(, 'empty_region_result', <Result>:)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

[histo_to_thresh](#), [threshold](#), [gen_region_histo](#)

Alternatives

[shape_histo_point](#)

Module

Foundation

```
shape_histo_point ( Region, Image : : Feature, Row,
                   Column : AbsoluteHisto, RelativeHisto )
```

Determine a histogram of features along all threshold values.

Like [shape_histo_all](#) the operator [shape_histo_point](#) carries out 255 threshold value operations within [Region](#) with the gray values of [Image](#). Contrary to [shape_histo_all](#) only the segmented region containing the pixel ([Row](#), [Column](#)) is taken into account here. The entry i in the histogram then corresponds to the number of holes of this region segmented with the threshold i ([Feature](#) = 'holes') or the feature value of the region ([Feature](#) = 'convexity', 'compactness', 'anisometry'), respectively.

Attention

Note that the operator [shape_histo_point](#) only considers the given [Region](#) and ignores any previously set domain of the input image [Image](#).

Parameters

- ▷ **Region** (input_object) region $\leadsto$ object
Region in which the features are to be examined.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte
Gray value image.
- ▷ **Feature** (input_control) string $\leadsto$ string
Feature to be examined.
Default: 'convexity'
List of values: Feature $\in$ {'convexity', 'compactness', 'anisometry', 'holes'}
- ▷ **Row** (input_control) point.y $\leadsto$ integer
Row of the pixel which the region must contain.
Default: 256
Suggested values: Row $\in$ {10, 50, 100, 200, 300, 400}
- ▷ **Column** (input_control) point.x $\leadsto$ integer
Column of the pixel which the region must contain.
Default: 256
Suggested values: Column $\in$ {10, 50, 100, 200, 300, 400}
- ▷ **AbsoluteHisto** (output_control) histogram-array $\leadsto$ real / integer
Absolute distribution of the feature.
- ▷ **RelativeHisto** (output_control) histogram-array $\leadsto$ real
Relative distribution of the feature.

Result

The operator [shape_histo_point](#) returns the value 2 (H_MSG_TRUE) if an image with defined gray values is entered. The behavior in case of empty input (no input images available) is set via the operator [set_system](#) (':no_object_result', <Result>:), the behavior in case of empty region is set via [set_system](#) (':empty_region_result', <Result>:). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

15.7 Format

add_image_border (*Image* : *ImageBorder* : *Size*, *Value* :)

Add a border to an image.

Adds a border to the input image [Image](#) and returns the resulting image in [ImageBorder](#).

The size of the border in pixels must be passed in [Size](#). It can be set as follows:

- Single number: Border size in all four directions left/right/top/bottom.
- Two numbers: Border size on left/right and top/bottom side: [*l*/*r*, *t*/*b*].
- Four numbers: Border size on left, right, top, bottom side: [*l*, *r*, *t*, *b*].

The gray value of the added border must be passed in [Value](#). It can be set as follows:

- Single number: Value will be applied to all channels of [Image](#).
- Multiple numbers: Values will be applied to the channels of the image separately. Thus, the first value will be applied to the first channel, the second value will be applied to the second channel and so on.

Restriction: Number of values must be equal to the number of channels.

Note that `add_image_border` will ignore the input domain and will always return an image with a full domain in [ImageBorder](#).

Parameters

- ▷ **Image** (input_object) multichannel-image-array $\leadsto$ *object* : byte / direction / int1 / int2 / uint2 / int4 / int8 / real
Input image.
- ▷ **ImageBorder** (output_object) multichannel-image-array $\leadsto$ *object* : byte / direction / int1 / int2 / uint2 / int4 / int8 / real
Output image.
- ▷ **Size** (input_control) attribute.name(-array) $\leadsto$ *integer*
Size of the border in pixels.
Default: 10
- ▷ **Value** (input_control) attribute.name(-array) $\leadsto$ *integer* / string
Gray value of the border.
Default: 100

Example

```
* Add a border of 20 pixels with a constant gray value of 255
* on all four sides of Image
read_image (Image, 'printer_chip/printer_chip_01')
add_image_border (Image, ImageBorder, 20, 255)

* Add a 10-pixel border with a constant gray value of 255 to
* the left and right side and a 20-pixel border with the same
* gray value to the top and bottom of Image.
read_image (Image, 'printer_chip/printer_chip_01')
add_image_border (Image, ImageBorder, [10, 20], 255)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Alternatives

`tile_images_offset`

Module

Foundation

change_format (Image : ImagePart : Width, Height :)
--

Change image size.

The operator `change_format` increases or decreases the size of the input images to the indicated height or width, respectively. If the image is reduced, parts are cut off at the “right” or “lower” edge of the image, respectively. If the image is enlarged, the additional areas are set to 0. The definition domain of the new image is equal to the domain of the input image, clipped to the size of the new image. No zooming is carried out.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Input image.
- ▷ **ImagePart** (output_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Image with new format.
- ▷ **Width** (input_control) extent.x $\leadsto$ *integer*
Width of new image.
Default: 512
Suggested values: Width $\in$ {32, 64, 128, 256, 512, 768, 1024}
- ▷ **Height** (input_control) extent.y $\leadsto$ *integer*
Height of new image.
Default: 512
Suggested values: Height $\in$ {32, 64, 128, 256, 512, 525, 1024}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

	Module
Foundation	

```
crop_domain ( Image : ImagePart : : )
```

Cut out of defined gray values.

The operator `crop_domain` cuts a rectangular area from the input images. This rectangle is the smallest surrounding rectangle of the domain of the input image. The new image matrix has the size of the rectangle.

	Parameters
▷ Image (input_object) (multichannel-)image(-array) $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real	
Input image.	
▷ ImagePart (output_object) (multichannel-)image(-array) $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real	
Image area.	
	Execution Information

- Supports OpenCL compute devices.

zoom_image_size , zoom_image_factor	
	Module
Foundation	

```
crop_domain_rel ( Image : ImagePart : Top, Left, Bottom,
                  Right : )
```

Cut out an image area relative to the domain.

`crop_domain_rel` cuts a rectangular area from the input images. The area is determined by the surrounding rectangle of the domain of the input image. The rectangle can be influenced by the control parameters to modify at the top ([Top](#)), at the left ([Left](#)), at the bottom ([Bottom](#)), and at the right ([Right](#)). Positive values results in a smaller, negative values in a larger size. If all parameters are set to zero, the region remains unchanged.

	Parameters
▷ Image (input_object) (multichannel-)image(-array) $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real	
Input image.	

- ▷ **ImagePart** (output_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
- Image area.
- ▷ **Top** (input_control) integer $\leadsto$ *integer*
Number of rows clipped at the top.
Default: -1
Suggested values: Top $\in \{-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **Left** (input_control) integer $\leadsto$ *integer*
Number of columns clipped at the left.
Default: -1
Suggested values: Left $\in \{-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **Bottom** (input_control) integer $\leadsto$ *integer*
Number of rows clipped at the bottom.
Default: -1
Suggested values: Bottom $\in \{-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **Right** (input_control) integer $\leadsto$ *integer*
Number of columns clipped at the right.
Default: -1
Suggested values: Right $\in \{-20, -10, -5, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}$

Result

crop_domain_rel returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result', <Result>)` and the behavior in case of an empty input region via `set_system('empty_region_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Module

Foundation

crop_part (Image : ImagePart : Row, Column, Width, Height :)

Cut out one or more rectangular image areas.

The operator `crop_part` cuts one or more rectangular area from each of the input images. The areas are indicated by rectangles, which are defined by the coordinates of their upper left corner and by their size. The upper left corners of the rectangles must be within the image. At the right side and at the bottom, the rectangles may exceed the image, but the domain of the output images is set so that only the part that can be derived from the input image is contained. If the rectangular areas fall completely within the image, then each of the resulting images has the size of its corresponding rectangle.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Input image.
- ▷ **ImagePart** (output_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Image area.
- ▷ **Row** (input_control) rectangle.origin.y(-array) $\leadsto$ *integer*
Line index of upper left corner of image area.
Default: 100
Suggested values: Row $\in$ {10, 20, 50, 100, 200, 300, 500}
Value range: $0 \leq \text{Row} \leq 1024$
- ▷ **Column** (input_control) rectangle.origin.x(-array) $\leadsto$ *integer*
Column index of upper left corner of image area.
Default: 100
Suggested values: Column $\in$ {10, 20, 50, 100, 200, 300, 500}
Value range: $0 \leq \text{Column} \leq 1024$
- ▷ **Width** (input_control) rectangle.extent.x(-array) $\leadsto$ *integer*
Width of new image.
Default: 128
Suggested values: Width $\in$ {32, 64, 128, 256, 512, 768}
Value range: $0 \leq \text{Width} \leq 1024$
- ▷ **Height** (input_control) rectangle.extent.y(-array) $\leadsto$ *integer*
Height of new image.
Default: 128
Suggested values: Height $\in$ {32, 64, 128, 256, 512, 525}
Value range: $0 \leq \text{Height} \leq 1024$

Module

Foundation

```
crop_rectangle1 ( Image : ImagePart : Row1, Column1, Row2,
                  Column2 : )
```

Cut out one or more rectangular image areas.

The operator `crop_rectangle1` cuts one or more rectangular areas from each of the input images. The areas are indicated by rectangles, which are defined by the coordinates of their upper left and their lower right corners. The upper left corners must be within the image. At the right side and at the bottom, the rectangles may exceed the image, but the domain of the output images is set so that only the part that can be derived from the input image is contained. If the rectangular areas fall within the image, then each of the resulting images has the size of its corresponding rectangle.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Input image.
- ▷ **ImagePart** (output_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Image area.
- ▷ **Row1** (input_control) rectangle.origin.y(-array) $\leadsto$ *integer*
Line index of upper left corner of image area.
Default: 100
Suggested values: Row1 $\in$ {10, 20, 50, 100, 200, 300, 500}
Value range: $0 \leq \text{Row1} \leq 1024$
- ▷ **Column1** (input_control) rectangle.origin.x(-array) $\leadsto$ *integer*
Column index of upper left corner of image area.
Default: 100
Suggested values: Column1 $\in$ {10, 20, 50, 100, 200, 300, 500}
Value range: $0 \leq \text{Column1} \leq 1024$
- ▷ **Row2** (input_control) rectangle.corner.y(-array) $\leadsto$ *integer*
Line index of lower right corner of image area.
Default: 200
Suggested values: Row2 $\in$ {10, 20, 50, 100, 200, 300, 500}
Value range: $0 \leq \text{Row2} \leq 1024$
- ▷ **Column2** (input_control) rectangle.corner.x(-array) $\leadsto$ *integer*
Column index of lower right corner of image area.
Default: 200
Suggested values: Column2 $\in$ {10, 20, 50, 100, 200, 300, 500}
Value range: $0 \leq \text{Column2} \leq 1024$

Module

Foundation

crop_rectangle2 (Image : ImagePart : Row, Column, Phi, Length1, Length2, AlignToAxis, Interpolation :)

Cut out one or more arbitrarily oriented rectangular image areas.

`crop_rectangle2` cuts one or more rectangular areas from each of the input images. The areas are indicated by rectangles, which are defined by the center ([Row](#), [Column](#)), the orientation [Phi](#) and the half edge lengths [Length1](#) and [Length2](#). [Phi](#) is given in arc measure in mathematically positive direction and indicates the angle between the horizontal axis and the first edge (with length [Length1](#)). The rectangle parameters use pixel centered, subpixel accurate coordinates, see [Transformations / 2D Transformations](#).

The parameter [AlignToAxis](#) determines the alignment of the output image. Possible values:

- **'true'**: The cropped image part is rotated such that it is aligned with the coordinate axes. For this, a suitable interpolation must be performed. A detailed description of the interpolation modes can be found in the description of [affine_trans_image](#). The rectangle may protrude the input image. Gray values of pixels lying outside the input image are set to 0.
- **'false'**: The smallest surrounding rectangle of the input rectangle is cut out and the domain is set accordingly. The rectangle may exceed the input image boundaries. However, the size of the resulting cropped image part is determined by the portion of the rectangle which lies within the input image boundaries. For this method no interpolation is required. Therefore, the parameter [Interpolation](#) has no effect.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / int2 / uint2 / real
Input image(s).
- ▷ **ImagePart** (output_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / int2 / uint2 / real
Cropped image part(s).
- ▷ **Row** (input_control) rectangle2.center.y(-array) $\leadsto$ *real* / integer
Row index of the image crop center.
Default: 300.0
Suggested values: Row $\in$ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
(lin)
Recommended increment: 10.0
- ▷ **Column** (input_control) rectangle2.center.x(-array) $\leadsto$ *real* / integer
Column index of the image crop center.
Default: 200.0
Suggested values: Column $\in$ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
(lin)
Recommended increment: 10.0
- ▷ **Phi** (input_control) rectangle2.angle.rad(-array) $\leadsto$ *real* / integer
Orientation of the rectangle (arc measure).
Default: 0.0
Suggested values: Phi $\in$ {-1.178097, -0.785398, -0.392699, 0.0, 0.392699, 0.785398, 1.178097}
Value range: $-1.178097 \leq \text{Phi} \leq 1.178097$ (lin)
- ▷ **Length1** (input_control) rectangle2.hwidth(-array) $\leadsto$ *real* / integer
First half edge length of the rectangle.
Default: 100.0
Suggested values: Length1 $\in$ {3.0, 5.0, 10.0, 15.0, 20.0, 50.0, 100.0, 200.0, 300.0, 500.0}
(lin)
Recommended increment: 10.0
- ▷ **Length2** (input_control) rectangle2.hheight(-array) $\leadsto$ *real* / integer
Second half edge length of the rectangle.
Default: 20.0
Suggested values: Length2 $\in$ {1.0, 2.0, 3.0, 5.0, 10.0, 15.0, 20.0, 50.0, 100.0, 200.0}
(lin)
Recommended increment: 10.0
- ▷ **AlignToAxis** (input_control) string $\leadsto$ *string*
Determines whether the cropped image part is aligned with the coordinate axes.
Default: 'true'
List of values: AlignToAxis $\in$ {'true', 'false'}
- ▷ **Interpolation** (input_control) string $\leadsto$ *string*
Interpolation method.
Default: 'constant'
List of values: Interpolation $\in$ {'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'}
-

Execution Information

tile_channels (Image : TiledImage : NumColumns, TileOrder :)

Tile multiple images into a large image.

`tile_channels` tiles an image consisting of multiple channels into a large single-channel image. The input image `Image` contains *Num* images of the same size, which are stored in the individual channels. The output image `TiledImage` contains a single channel image, where the *Num* input channels have been tiled into `NumColumns` columns. In particular, this means that `tile_channels` cannot tile color images. For this purpose, `tile_images` can be used. The parameter `TileOrder` determines the order in which the images are copied into the output in the cases in which this is not already determined by `NumColumns` (i.e., if `NumColumns` != 1 and `NumColumns` != *Num*). If `TileOrder` = 'horizontal' the images are copied in the horizontal direction, i.e., the second channel of `Image` will be to the right of the first channel. If `TileOrder` = 'vertical' the images are copied in the vertical direction, i.e., the second channel of `Image` will be below the first channel. The domain of `TiledImage` is obtained by copying the domain of `Image` to the corresponding locations in the output image. If *Num* is not a multiple of `NumColumns` the output image will have undefined gray values in the lower right corner of the image. The output domain will reflect this.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Input image.
- ▷ **TiledImage** (output_object) singlechannelimage(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Tiled output image.
- ▷ **NumColumns** (input_control) integer $\leadsto$ *integer*
Number of columns to use for the output image.
Default: 1
Suggested values: `NumColumns` ∈ {1, 2, 3, 4, 5, 6, 7}
Restriction: `NumColumns` ≥ 1
- ▷ **TileOrder** (input_control) string $\leadsto$ *string*
Order of the input images in the output image.
Default: 'vertical'
List of values: `TileOrder` ∈ {'horizontal', 'vertical'}

Example

```
* Grab 5 single-channel images and stack them vertically.
gen_rectangle1 (Image, 0, 0, Height-1, Width-1)
for I := 1 to 5 by 1
    grab_image_async (ImageGrabbed, AcqHandle, -1)
    append_channel (Image, ImageGrabbed, Image)
endfor
tile_channels (Image, TiledImage, 1, 'vertical')
```

Result

`tile_channels` returns 2 (`H_MSG_TRUE`) if all parameters are correct and no error occurs during execution.

If the input is empty the behavior can be set via `set_system( : : 'no_object_result' , <Result> : )`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

tile_images (Images : TiledImage : NumColumns, TileOrder :)

Tile multiple image objects into a large image.

`tile_images` tiles multiple input image objects, which must contain the same number of channels, into a large image. The input image object `Images` contains `Num` images, which may be of different size. The output image `TiledImage` contains as many channels as the input images. In the output image the `Num` input images have been tiled into `NumColumns` columns. Each tile has the same size, which is determined by the maximum width and height of all input images. If an input image is smaller than the tile size it is copied to the center of the respective tile. The parameter `TileOrder` determines the order in which the images are copied into the output in the cases in which this is not already determined by `NumColumns` (i.e., if `NumColumns` != 1 and `NumColumns` != `Num`). If `TileOrder` = 'horizontal' the images are copied in the horizontal direction, i.e., the second image of `Images` will be to the right of the first image. If `TileOrder` = 'vertical' the images are copied in the vertical direction, i.e., the second image of `Images` will be below the first image. The domain of `TiledImage` is obtained by copying the domains of `Images` to the corresponding locations in the output image. If `Num` is not a multiple of `NumColumns` the output image will have undefined gray values in the lower right corner of the image. The output domain will reflect this.

Parameters

- ▷ **Images** (input_object) (multichannel-)image-array $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Input images.
- ▷ **TiledImage** (output_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Tiled output image.
- ▷ **NumColumns** (input_control) integer $\leadsto$ *integer*
Number of columns to use for the output image.
Default: 1
Suggested values: NumColumns $\in$ { 1, 2, 3, 4, 5, 6, 7 }
Restriction: NumColumns $\geq$ 1
- ▷ **TileOrder** (input_control) string $\leadsto$ *string*
Order of the input images in the output image.
Default: 'vertical'
List of values: TileOrder $\in$ { 'horizontal', 'vertical' }

Example

```
* Grab 5 (multi-channel) images and stack them vertically.
gen_empty_obj (Images)
```

```

for I := 1 to 5 by 1
    grab_image_async (ImageGrabbed, AcqHandle, -1)
    concat_obj (Images, ImageGrabbed, Images)
endfor
tile_images (Images, TiledImage, 1, 'vertical')

```

Result

`tile_images` returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via `set_system(:'no_object_result', <Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

tile_images_offset (Images : TiledImage : OffsetRow, OffsetCol,
Row1, Col1, Row2, Col2, Width, Height :)

Tile multiple image objects into a large image with explicit positioning information.

`tile_images_offset` tiles multiple input image objects, which must contain the same number of channels, into a large image. The input image object `Images` contains `Num` images, which may be of different size. The output image `TiledImage` contains as many channels as the input images. The size of the output image is determined by the parameters `Width` and `Height`. The position of the upper left corner of the input images in the output images is determined by the parameters `OffsetRow` and `OffsetCol`. Both parameters must contain exactly `Num` values. Optionally, each input image can be cropped to an arbitrary rectangle that is smaller than the input image. To do so, the parameters `Row1`, `Col1`, `Row2`, and `Col2` must be set accordingly. If any of these four parameters is set to `-1`, the corresponding input image is not cropped. In any case, all four parameters must contain `Num` values. If the input images are cropped the position parameters `OffsetRow` and `OffsetCol` refer to the upper left corner of the cropped image. If the input images overlap each other in the output image (while taking into account their respective domains), the image with the higher index in `Images` overwrites the image data of the image with the lower index. The domain of `TiledImage` is obtained by copying the domains of `Images` to the corresponding locations in the output image.

Attention

If the input images all have the same size and tile the output image exactly, the operator `tile_images` usually will be slightly faster.

Parameters

- ▷ **Images** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Input images.
- ▷ **TiledImage** (output_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Tiled output image.

- ▷ **OffsetRow** (input_control) point.y(-array) $\leadsto$ *integer*
Row coordinate of the upper left corner of the input images in the output image.
Default: 0
Suggested values: OffsetRow $\in$ {0, 50, 100, 150, 200, 250}
- ▷ **OffsetCol** (input_control) point.x(-array) $\leadsto$ *integer*
Column coordinate of the upper left corner of the input images in the output image.
Default: 0
Suggested values: OffsetCol $\in$ {0, 50, 100, 150, 200, 250}
- ▷ **Row1** (input_control) rectangle.origin.y(-array) $\leadsto$ *integer*
Row coordinate of the upper left corner of the copied part of the respective input image.
Default: -1
Suggested values: Row1 $\in$ {-1, 0, 10, 20, 50, 100, 200, 300, 500}
- ▷ **Col1** (input_control) rectangle.origin.x(-array) $\leadsto$ *integer*
Column coordinate of the upper left corner of the copied part of the respective input image.
Default: -1
Suggested values: Col1 $\in$ {-1, 0, 10, 20, 50, 100, 200, 300, 500}
- ▷ **Row2** (input_control) rectangle.corner.y(-array) $\leadsto$ *integer*
Row coordinate of the lower right corner of the copied part of the respective input image.
Default: -1
Suggested values: Row2 $\in$ {-1, 0, 10, 20, 50, 100, 200, 300, 500}
- ▷ **Col2** (input_control) rectangle.corner.x(-array) $\leadsto$ *integer*
Column coordinate of the lower right corner of the copied part of the respective input image.
Default: -1
Suggested values: Col2 $\in$ {-1, 0, 10, 20, 50, 100, 200, 300, 500}
- ▷ **Width** (input_control) extent.x $\leadsto$ *integer*
Width of the output image.
Default: 512
Suggested values: Width $\in$ {32, 64, 128, 256, 512, 768, 1024, 2048, 4096}
- ▷ **Height** (input_control) extent.y $\leadsto$ *integer*
Height of the output image.
Default: 512
Suggested values: Height $\in$ {32, 64, 128, 256, 512, 525, 1024, 2048, 4096}

Example

```

* Example 1
* Grab 2 (multi-channel) NTSC images, crop the bottom 5 lines off
* of each image, the right 5 columns off of the first image, and
* the left five lines off of the second image, and put the cropped
* images side-by-side.
gen_empty_obj (Images)
for I := 1 to 2 by 1
    grab_image_async (ImageGrabbed, AcqHandle, -1)
    concat_obj (Images, ImageGrabbed, Images)
endfor
tile_images_offset (Images, TiledImage, [0,635], [0,0], [0,0], \
    [0,5], [474,474], [634,639], 635, 950)

```

```

* Example 2
* Enlarge image by 15 rows and columns on all sides
EnlargeColsBy := 15
EnlargeRowsBy := 15
get_image_pointer1 (Image, Pointer, Type, WidthImage, HeightImage)
tile_images_offset (Image, EnlargedImage, EnlargeRowsBy, EnlargeColsBy, \
    -1, -1, -1, -1, WidthImage + EnlargeColsBy*2, \
    HeightImage + EnlargeRowsBy*2)

```

Result

tile_images_offset returns 2 (H_MSG_TRUE) if all parameters are correct and no error oc-

curs during execution. If the input is empty the behavior can be set via `set_system(:,:, 'no_object_result', <Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

15.8 Manipulation

overpaint_gray (ImageDestination, ImageSource : : :)

Overpaint the gray values of an image.

`overpaint_gray` copies the gray values of the image given in `ImageSource` into the image in `ImageDestination`. Only the gray values of the domain of `ImageSource` are copied (see `reduce_domain`).

If you do not want to modify `ImageDestination` itself, you can use the operator `paint_gray`, which returns the result in a newly created image.

Attention

`overpaint_gray` modifies the content of an already existing image (`ImageDestination`). Besides, even other image objects may be affected: For example, if you created `ImageDestination` via `copy_obj` from another image object (or vice versa), `overpaint_gray` will also modify the image matrix of this other image object. Therefore, `overpaint_gray` should only be used to overpaint newly created image objects. Typical operators for this task are, e.g., `gen_image_const` (creates a new image with a specified size), `gen_image_proto` (creates an image with the size of a specified prototype image) or `copy_image` (creates an image as the copy of a specified image).

Parameters

▷ **ImageDestination** (input_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field

Input image to be painted over.

▷ **ImageSource** (input_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field

Input image containing the desired gray values.

Example

* Copy a circular part of the image 'monkey' into a new image (New1):

```
read_image(Image, 'monkey')
gen_circle(Circle, 200, 200, 150)
reduce_domain(Image, Circle, Mask)
* New image with black (0) background
gen_image_proto(Image, New1, 0.0)
* Copy a part of the image 'monkey' into New1
overpaint_gray(New1, Mask)
```

Result

`overpaint_gray` returns 2 (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ImageDestination`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`paint_region`, `overpaint_region`

Module

Foundation

<code>overpaint_region</code> (<code>Image</code> , <code>Region</code> : : <code>Grayval</code> , <code>Type</code> :)
--

Overpaint regions in an image.

`overpaint_region` paints the regions given in `Region` with a constant gray value into the image given in `Image`. These gray values can either be specified for each channel once, valid for all regions, or for each region separately. To define the latter, group the channel gray values *g* of each region and concatenate them to a tuple according to the regions' order, e.g., for a three channel image:

$$[g(\text{channel1}, \text{region1}), g(\text{channel2}, \text{region1}), g(\text{channel3}, \text{region1}), g(\text{channel1}, \text{region2}), \dots]$$

If the input image is of type `direction`, gray values that are not in the value range that is valid for `direction` images are set to the value 255 to mark them as invalid. The parameter `Type` determines whether the region should be painted filled ('*fill*') or whether only its boundary should be painted ('*margin*').

If you do not want to modify `Image` itself, you can use the operator `paint_region`, which returns the result in a newly created image.

Attention

`overpaint_region` modifies the content of an already existing image (`Image`). Besides, even other image objects may be affected: For example, if you created `Image` via `copy_obj` from another image object (or vice versa), `overpaint_region` will also modify the image matrix of this other image object. Therefore, `overpaint_region` should only be used to overpaint newly created image objects. Typical operators for this task are, e.g., `gen_image_const` (creates a new image with a specified size), `gen_image_proto` (creates an image with the size of a specified prototype image) or `copy_image` (creates an image as the copy of a specified image).

Parameters

- ▷ **Image** (input_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
- Image in which the regions are to be painted.
- ▷ **Region** (input_object) region(-array) $\leadsto$ *object*
- Regions to be painted into the input image.

- ▷ **Grayval** (input_control) number(-array) $\leadsto$ real / integer
Desired gray values of the regions.
Default: 255.0
Suggested values: Grayval $\in$ {0.0, 1.0, 2.0, 5.0, 10.0, 16.0, 32.0, 64.0, 128.0, 253.0, 254.0, 255.0}
- ▷ **Type** (input_control) string $\leadsto$ string
Paint regions filled or as boundaries.
Default: 'fill'
List of values: Type $\in$ {'fill', 'margin'}

Example

```
* Paint a rectangle into a new image (New1)

gen_rectangle1 (Rectangle, 100.0, 100.0, 300.0, 300.0)
* generate a black image
gen_image_const (New1, 'byte', 768, 576)
* paint a white rectangle
overpaint_region (New1, Rectangle, 255.0, 'fill')
```

Result

overpaint_region returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system(, 'no_object_result', <Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- Image

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

paint_gray (ImageSource, ImageDestination : MixedImage : :)
--

Paint the gray values of an image into another image.

`paint_gray` paints the gray values of the image given in `ImageSource` into the image in `ImageDestination` and returns the resulting image in `MixedImage`. Only the gray values of the domain of `ImageSource` are copied (see `reduce_domain`).

As an alternative to `paint_gray`, you can use the operator `overpaint_gray`, which directly paints the gray values into `ImageDestination`.

Parameters

- ▷ **ImageSource** (input_object) (multichannel-)image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
- Input image containing the desired gray values.
- ▷ **ImageDestination** (input_object) (multichannel-)image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
- Input image to be painted over.
- ▷ **MixedImage** (output_object) image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
- Result image.

Example

* Copy a circular part of the image 'monkey' into the image 'fabrik':

```
read_image(Image, 'monkey')
gen_circle(Circle, 200, 200, 150)
reduce_domain(Image, Circle, Mask)
read_image(Image2, 'fabrik')
* Copy a part of the image 'monkey' into 'fabrik'
paint_gray(Mask, Image2, MixedImage)
```

Result

paint_gray returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

paint_region (Region, Image : ImageResult : Grayval, Type :)

Paint regions into an image.

paint_region paints the regions given in [Region](#) with a constant gray value into the image given in [Image](#) and returns the result in [ImageResult](#). These gray values can either be specified for each channel once, valid for all regions, or for each region separately. To define the latter, group the channel gray values *g* of each region and concatenate them to a tuple according to the regions' order, e.g., for a three channel image:

$$[g(\text{channel1}, \text{region1}), g(\text{channel2}, \text{region1}), g(\text{channel3}, \text{region1}), g(\text{channel1}, \text{region2}), \dots]$$

If the input image is of type [direction](#), gray values that are not in the value range that is valid for [direction](#) images are set to the value 255 to mark them as invalid. The parameter [Type](#) determines whether the region should be painted filled ('*fill*') or whether only its boundary should be painted ('*margin*').

As an alternative to `paint_region`, you can use the operator `overpaint_region`, which directly paints the regions into `Image`.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be painted into the input image.
- ▷ **Image** (input_object) (multichannel-)image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
Image in which the regions are to be painted.
- ▷ **ImageResult** (output_object) image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex
Image containing the result.
- ▷ **Grayval** (input_control) number(-array) $\leadsto$ real / integer
Desired gray values of the regions.
Default: 255.0
Suggested values: Grayval $\in$ {0.0, 1.0, 2.0, 5.0, 10.0, 16.0, 32.0, 64.0, 128.0, 253.0, 254.0, 255.0}
- ▷ **Type** (input_control) string $\leadsto$ string
Paint regions filled or as boundaries.
Default: 'fill'
List of values: Type $\in$ {'fill', 'margin'}

Example

```
* Paint a rectangle into the image 'monkey'

read_image(Image, 'monkey')
gen_rectangle1(Rectangle, 100.0, 100.0, 300.0, 300.0)
* paint a white rectangle
paint_region(Rectangle, Image, ImageResult, 255.0, 'fill')
```

Result

`paint_region` returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system(, 'no_object_result', <Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`reduce_domain`, `paint_gray`, `overpaint_gray`, `set_draw`, `gen_image_const`

Module

Foundation

paint_xld (XLD, Image : ImageResult : Grayval :)

Paint XLD objects into an image.

`paint_xld` paints the XLD objects `XLD` of type contour or polygon with the constant gray values `Grayval` into each channel of the background image given in `Image` and returns the result in `ImageResult`. Open contours

of XLD objects are closed and their enclosed regions are filled up. The rim of the subpixel XLD objects is painted onto the background image using anti-aliasing.

Filling up XLD-objects that have crossings or segments that are very close (lying in neighboring pixels) does not work correctly and leads to artifacts. The `set_system` parameter `'neighborhood'` defines whether diagonal neighbors are filled as well as orthogonal neighbors.

`Grayval` contains the gray values for painting the XLD objects. These gray values can either be specified for each channel once, valid for all XLD objects, or for each XLD object separately. To define the latter, group the channel gray values g of each XLD object and concatenate them to a tuple according to the order of the XLD objects, e.g., for a three channel image:

$$[g(\text{channel1}, \text{xld1}), g(\text{channel2}, \text{xld1}), g(\text{channel3}, \text{xld1}), g(\text{channel1}, \text{xld2}), \dots]$$

If the input image is of type `direction`, gray values that are not in the value range that is valid for `direction` images are set to the value 255 to mark them as invalid.

Parameters

- ▷ **XLD** (input_object) xld(-array) $\leadsto$ object
XLD objects to be painted into the input image.
- ▷ **Image** (input_object) (multichannel-)image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex
Image in which the xld objects are to be painted.
- ▷ **ImageResult** (output_object) image $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex
Image containing the result.
- ▷ **Grayval** (input_control) number(-array) $\leadsto$ real / integer
Desired gray value of the xld object.
Default: 255.0
Suggested values: $\text{Grayval} \in \{0.0, 1.0, 2.0, 5.0, 10.0, 16.0, 32.0, 64.0, 128.0, 253.0, 254.0, 255.0\}$

Example

```
* Paint colored xld objects into a gray image

* read and copy image to generate a three channel image
read_image(Image1, 'green-dot')
copy_image(Image1, Image2)
copy_image(Image1, Image3)
compose3(Image1, Image2, Image3, Image)
* extract subpixel border
threshold_sub_pix(Image1, Border, 128)
* select the circle and the arrows
select_obj(Border, circle, 14)
select_obj(Border, arrows, 16)
concat_obj(circle, arrows, green_dot)
* paint a green circle and white arrows (to paint all
* objects e.g., blue, pass [0,0,255] tuple for GrayVal)
paint_xld(green_dot, Image, ImageResult, [0, 255, 0, 255, 255, 255])
```

Result

`paint_xld` returns 2 (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system(::'no_object_result', <Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`threshold_sub_pix`

Alternatives

`set_grayval`, `paint_gray`, `paint_region`

See also

`gen_image_const`

Module

Foundation

set_grayval (Image : : Row, Column, Grayval :)

Set single gray values in an image.

`set_grayval` sets the gray values of the input image `Image` at the positions (`Row`, `Column`) to the values specified by `Grayval`. If `Image` is a multi-channel image, you can either set a single gray value for a pixel and thus set it for all available channels, or you can set the gray values `g` for all channels individually by concatenating them within `Grayval`. For example, for a three-channel image three gray values (according to the order of the channels) are specified for each pixel:

$$[g(\text{channel0}, \text{pixel0}), g(\text{channel1}, \text{pixel0}), g(\text{channel2}, \text{pixel0}), g(\text{channel0}, \text{pixel1}), \dots]$$

Please note that for complex or vector field images, two gray values per pixel must be specified (per channel).

If the image is of type `direction`, gray values that are not in the value range that is valid for `direction` images are set to the value 255 to mark them as invalid.

Attention

The operator `set_grayval` produces quite some overhead. Typically, it is used to set single gray values of an image. It is not suitable for programming image processing operations such as filters. In this case it is more useful to use the operator `get_image_pointer1` and to directly use the C or C++ interface for integrating own procedures.

Note also that `set_grayval` modifies the content of an already existing image (`Image`). Besides, even other image objects may be affected: For example, if you created `Image` via `copy_obj` from another image object, `set_grayval` will also modify the image matrix of this other image object. Therefore, `set_grayval` should only be used to overpaint newly created image objects.

Parameters

- ▷ **Image** (input_object) (multichannel-)image $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
 Image to be modified.
- ▷ **Row** (input_control) point.y(-array) $\leadsto$ *integer*
 Row coordinates of the pixels to be modified.
Default: 0
Suggested values: `Row` $\in$ {0, 10, 50, 127, 255, 511}
Value range: $0 \leq \text{Row}$
Restriction: $0 \leq \text{Row} \ \&\& \ \text{Row} < \text{height}(\text{Image})$
- ▷ **Column** (input_control) point.x(-array) $\leadsto$ *integer*
 Column coordinates of the pixels to be modified.
Default: 0
Suggested values: `Column` $\in$ {0, 10, 50, 127, 255, 511}
Value range: $0 \leq \text{Column}$
Restriction: $0 \leq \text{Column} \ \&\& \ \text{Column} < \text{width}(\text{Image})$
- ▷ **Grayval** (input_control) grayval(-array) $\leadsto$ *real* / *integer*
 Gray values to be used.
Default: 255.0
Suggested values: `Grayval` $\in$ {0.0, 1.0, 10.0, 128.0, 255.0}

Result

`set_grayval` returns 2 (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system(:, 'no_object_result', <Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- Image

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

15.9 Type Conversion

<code>complex_to_real</code> (<code>ImageComplex</code> : <code>ImageReal</code> , <code>ImageImaginary</code> : :)
--

Convert a complex image into two real images.

`complex_to_real` converts a complex image `ImageComplex` into two real images `ImageReal` and `ImageImaginary`, which contain the real and imaginary part of the complex image.

Parameters

- ▷ **`ImageComplex`** (input_object) `singlechannelimage(-array)` $\leadsto$ *object* : complex
Complex image.
- ▷ **`ImageReal`** (output_object) `image(-array)` $\leadsto$ *object* : real
Real part.
- ▷ **`ImageImaginary`** (output_object) `image(-array)` $\leadsto$ *object* : real
Imaginary part.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

See also

`real_to_complex`

Module

Foundation

```
convert_image_type ( Image : ImageConverted : NewType : )
```

Convert the type of an image.

`convert_image_type` converts images of an arbitrary type into an arbitrary new image type. If the conversion is done from a larger to a smaller gray value range (e.g., from 'int4' to 'byte'), too large or too small values are simply “clipped”. If the result images are of type 'direction', gray values that are not in the value range that is valid for 'direction' images are set to the value 255 to mark them as invalid. It is therefore advisable to adapt the range of gray values by calling `scale_image` before calling this operator. For images of type complex, only the real part is converted. The imaginary part is ignored. This facilitates an efficient conversion of images that have been transformed back from the frequency domain. Such images always have an imaginary part of 0.

Attention

The conversion to the 'int8' image format is only available on 64 bit systems! If the source and destination image type are identical, no new image matrix is allocated.

Parameters

▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex

Image whose image type is to be changed.

▷ **ImageConverted** (output_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex

Converted image.

▷ **NewType** (input_control) string $\leadsto$ *string*
Desired image type (i.e., type of the gray values).

Default: 'byte'

List of values: NewType $\in$ {'int1', 'int2', 'uint2', 'int4', 'int8', 'byte', 'real', 'direction', 'cyclic', 'complex'}

Result

`convert_image_type` returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module

Foundation

```
real_to_complex ( ImageReal, ImageImaginary : ImageComplex : : )
```

Convert two real images into a complex image.

`real_to_complex` converts two real images `ImageReal` and `ImageImaginary`, which contain the real and imaginary part of a complex image, into a complex image `ImageComplex`.

Parameters

- ▷ **ImageReal** (input_object)singlechannelimage(-array) $\leadsto$ *object* : real
Real part.
- ▷ **ImageImaginary** (input_object)singlechannelimage(-array) $\leadsto$ *object* : real
Imaginary part.
- ▷ **ImageComplex** (output_object)image(-array) $\leadsto$ *object* : complex
Complex image.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

real_to_vector_field (Row, Col : VectorField : Type :)

Convert two real-valued images into a vector field image.

`real_to_vector_field` converts two real-valued images `Row` and `Col` into a vector field image `VectorField`. The input images contain the vector components in the row and column direction, respectively. The semantic type of `VectorField` is set with `Type`.

Parameters

- ▷ **Row** (input_object)singlechannelimage(-array) $\leadsto$ *object* : real
Vector component in the row direction.
- ▷ **Col** (input_object)singlechannelimage(-array) $\leadsto$ *object* : real
Vector component in the column direction.
- ▷ **VectorField** (output_object)image(-array) $\leadsto$ *object* : vector_field
Displacement vector field.
- ▷ **Type** (input_control)string $\leadsto$ *string*
Semantic kind of the vector field.
Default: 'vector_field_relative'
List of values: Type $\in$ {'vector_field_relative', 'vector_field_absolute'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Chapter 16

Inspection

16.1 Bead Inspection

```
apply_bead_inspection_model ( Image : LeftContour, RightContour,  
ErrorSegment : BeadInspectionModel : ErrorType )
```

Inspect beads in an image, as defined by the bead inspection model.

The operator `apply_bead_inspection_model` applies the bead inspection model `BeadInspectionModel` to the input `Image`. The output parameter `ErrorSegment` indicates the positions of detected errors. The parameter `ErrorType` indicates the type of the detected errors for each segment. For more details on the possible errors, refer to the parameters' description and figures in `create_bead_inspection_model`. The value of `ErrorType` can be:

'no bead': No bead could be detected at this position.

'incorrect position': The center of the bead found at this position is further away from the contour than allowed by `PositionTolerance`.

'too thin': The bead is thinner than allowed by `TargetThickness` and `ThicknessTolerance`.

'too thick': The bead is thicker than allowed by `TargetThickness` and `ThicknessTolerance`.

Values of the generic parameters set through `create_bead_inspection_model` or `set_bead_inspection_param` highly affect the inspection results of the same model. For more details on those parameters, please refer to `create_bead_inspection_model`.

Note that the operator ignores the image domain and applies the model to the full image

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Image to apply bead inspection on.
- ▷ **LeftContour** (output_object) xld-array $\leadsto$ object
The detected left contour of the beads.
- ▷ **RightContour** (output_object) xld-array $\leadsto$ object
The detected right contour of the beads.
- ▷ **ErrorSegment** (output_object) xld-array $\leadsto$ object
Detected error segments
- ▷ **BeadInspectionModel** (input_control) bead_inspection_model $\leadsto$ handle
Handle of the bead inspection model to be used.
- ▷ **ErrorType** (output_control) string-array $\leadsto$ string
Types of detected errors.

Result

The operator `apply_bead_inspection_model` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `BeadInspectionModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

2D Metrology

<code>clear_bead_inspection_model</code> (: : <code>BeadInspectionModel</code> :)
--

Delete the bead inspection model and free the allocated memory.

The operator `clear_bead_inspection_model` deletes a bead inspection model that was created by [create_bead_inspection_model](#). All memory used by the model is freed. The handle of the model is passed in `BeadInspectionModel`. It is invalid after the operator call.

Parameters

- ▷ **`BeadInspectionModel`** (input_control) `bead_inspection_model` $\leadsto$ *handle*
 Handle of the bead inspection model.

Result

The operator `clear_bead_inspection_model` returns the value 2 (`H_MSG_TRUE`) if a valid handle is passed and the referred bead inspection model can be freed correctly. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `BeadInspectionModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

2D Metrology

```
create_bead_inspection_model ( BeadContour : : TargetThickness,
                               ThicknessTolerance, PositionTolerance, Polarity, GenParamName,
                               GenParamValue : BeadInspectionModel )
```

Create a model to inspect beads or adhesive in images.

`create_bead_inspection_model` creates a model to inspect beads or adhesive in images.

The basic principle of bead inspection

The bead inspection operators enable the user to define a reference contour that indicates the position and shape of a bead or adhesive on a certain product. Images of such products can then be inspected to verify that a bead or adhesive exists at the positions defined by the contour and that it is of acceptable thickness. The images must already be aligned with the given contour.

The operator `create_bead_inspection_model` returns a handle to the bead inspection model in `BeadInspectionModel`, which can later be used to perform other operations related to bead inspection. These operations include the modification of the bead inspection model parameters and performing the inspection on input images as defined by the model.

Providing the model contour

In order to inspect beads, a contour serving as the model for the bead must be provided in `BeadContour`. Such a contour can be generated, e.g., by using the operators `gen_contour_polygon_xld` or `gen_contour_nurbs_xld`. The contour must be defined to be aligned to the beads in the input images. To achieve this, the user can draw the XLD directly on a reference image in the graphics window (with `draw_polygon` or `draw_nurbs`). To inspect beads consisting of multiple parts, multiple models must be created.

Mandatory parameters

The mandatory parameters for a bead inspection model

In order to inspect beads, the following parameters must be set:

TargetThickness: defines the optimal bead thickness in pixels.

ThicknessTolerance: defines the tolerance to the bead's thickness in pixels. The bead is accepted if its thickness is within the range:

[[TargetThickness-ThicknessTolerance](#), [TargetThickness+ThicknessTolerance](#)]

PositionTolerance: defines the tolerance to the bead's position in pixels. The 'bead position' is the center of the detected bead. The bead is accepted if the distance between its center and the contour's position is less than the [PositionTolerance](#).

Polarity: defines the polarity of the bead in the images to inspect. 'light' if the bead is lighter than its background, 'dark' otherwise.

Edge extraction parameters

Bead inspection relies on edge extraction to identify the edges of beads. Accordingly, correct initialization of the [measure_pos](#) parameters helps improve bead inspection results.

The following parameters can be set for [GenParamName](#).

'sigma': Sets the standard deviation of the Gaussian smoothing kernel. The value of 'sigma' depends on the quality of the images to be inspected, namely on the amount of noise.

Default: 2.0

'threshold': Sets the minimum edge amplitude to be extracted. Setting a higher value for 'threshold' helps to avoid the extraction of noise edges and select salient edges. 'threshold' cannot be less than 1.

Default: 30

The Measure Assistant can be used to find suitable values for these two parameters.

Parameters

- ▷ **BeadContour** (input_object) xld $\leadsto$ object
XLD contour specifying the expected bead's shape and position.
- ▷ **TargetThickness** (input_control) integer $\leadsto$ integer / real
Optimal bead thickness.
Default: 50
Value range: $5 \leq \text{TargetThickness}$
- ▷ **ThicknessTolerance** (input_control) integer $\leadsto$ integer / real
Tolerance of bead's thickness with respect to [TargetThickness](#).
Default: 15
Value range: $0 \leq \text{ThicknessTolerance}$
- ▷ **PositionTolerance** (input_control) integer $\leadsto$ integer / real
Tolerance of the bead's center position.
Default: 15
Value range: $0 \leq \text{PositionTolerance}$
- ▷ **Polarity** (input_control) string $\leadsto$ string
The bead's polarity.
Default: 'light'
List of values: Polarity $\in$ {'light', 'dark'}
- ▷ **GenParamName** (input_control) attribute.name(-array) $\leadsto$ string
Names of the generic parameters that can be adjusted for the bead inspection model.
Default: []
List of values: GenParamName $\in$ {'sigma', 'threshold'}
- ▷ **GenParamValue** (input_control) attribute.value(-array) $\leadsto$ integer / real / string
Values of the generic parameters that can be adjusted for the bead inspection model.
Default: []
Suggested values: GenParamValue $\in$ {0.6, 1.0, 4.0, 5.0, 10.0, 50.0}
- ▷ **BeadInspectionModel** (output_control) bead_inspection_model $\leadsto$ handle
Handle for using and accessing the bead inspection model.

Example

```
* Read the image of the bead to be inspected.
read_image (Image, 'bead/adhesive_bead_01')
```

```

* Define the reference path of the adhesive beads.
gen_contour_nurbs_xld (ContourRef, \
    [610.974,533.443,461.763,393.009,330.106,287.683, \
    270.129,265.74,265.74,300.849,331.569,376.917, \
    438.357,489.557,539.294], \
    [418.581,424.27,439.441,473.574,526.67,574.078, \
    644.241,708.715,765.604,818.7,866.107,915.411, \
    966.611,998.848,993.159], \
    'auto', \
    [15,15,15,15,15,15,15,15,15,15,15,15,15,15,15], \
    3, 1, 5)

*
* Create the bead inspection model, identifying the bead's parameters
create_bead_inspection_model (ContourRef, 14, 7, 30, 'dark', [], [], \
    BeadInspectionModel)

*
* Apply the bead inspection model to the image
apply_bead_inspection_model (Image, LeftContour, RightContour, \
    ErrorSegment, BeadInspectionModel, \
    ErrorType)

```

Result

The operator `create_bead_inspection_model` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators. This operator modifies the state of the following input parameter:

- `BeadInspectionModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

2D Metrology

get_bead_inspection_param (: : <code>BeadInspectionModel</code> , GenParamName : GenParamValue)

Get the value of a parameter in a specific bead inspection model.

The operator `get_bead_inspection_param` is used to query the values of the different parameters of a bead inspection model. The names of the desired parameters are passed in the parameter `GenParamName`, the corresponding values are returned in `GenParamValue`. All these parameters can be set and changed at any time with the operator `set_bead_inspection_param`. Multiple parameters can be queried with a single call to `get_bead_inspection_param`.

The parameters that can be queried are `'target_thickness'`, `'thickness_tolerance'`, `'position_tolerance'`, `'polarity'`, `'sigma'` and `'threshold'`. Only the model's contour cannot be queried. Refer to [set_bead_inspection_param](#) and [create_bead_inspection_model](#) for a detailed description of all supported parameters.

Parameters

- ▷ **BeadInspectionModel** (input_control) `bead_inspection_model` $\leadsto$ *handle*
Handle of the bead inspection model.
- ▷ **GenParamName** (input_control) `attribute.name(-array)` $\leadsto$ *string*
Name of the model parameter that is queried.
Default: `'target_thickness'`
List of values: `GenParamName` $\in$ `{'target_thickness', 'thickness_tolerance', 'position_tolerance', 'polarity', 'sigma', 'threshold'}`
- ▷ **GenParamValue** (output_control) `attribute.value(-array)` $\leadsto$ *integer / real / string*
Value of the queried model parameter.

Result

The operator `get_bead_inspection_param` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

```
set_bead_inspection_param ( : : BeadInspectionModel, GenParamName,
    GenParamValue : )
```

Set parameters of the bead inspection model.

The operator `set_bead_inspection_param` is used to set parameters of a bead inspection model in order to adapt it to a particular inspection task. All parameters except for the model's contour can be set with this operator. A new bead inspection model should be used when a new contour is introduced. The current values of all parameters can be queried with the operator [get_bead_inspection_param](#).

Parameters that can be set

The following parameters are essential and inspection model specific. It is vital for the inspection's success to identify accurate values for those parameters:

- `'target_thickness'`: sets the `TargetThickness`.
- `'thickness_tolerance'`: sets the `ThicknessTolerance`.
- `'position_tolerance'`: sets the `PositionTolerance`.
- `'polarity'`: sets the bead's `Polarity`.
- `'sigma'`
- `'threshold'`

For more details, refer to the parameters' description in [create_bead_inspection_model](#).

Parameters

- ▷ **BeadInspectionModel** (input_control) bead_inspection_model $\leadsto$ *handle*
Handle of the bead inspection model.
- ▷ **GenParamName** (input_control) attribute.name(-array) $\leadsto$ *string*
Name of the model parameter that shall be adjusted for the specified bead inspection model.
Default: 'target_thickness'
List of values: GenParamName $\in$ {'target_thickness', 'thickness_tolerance', 'position_tolerance', 'polarity', 'sigma', 'threshold'}
- ▷ **GenParamValue** (input_control) attribute.value(-array) $\leadsto$ *string / integer / real*
Value of the model parameter that shall be adjusted for the specified bead inspection model.
Default: 40
Suggested values: GenParamValue $\in$ {40, 10, 15, 0.6, 1.0, 4.0, 5.0, 'light', 'dark'}

Result

The operator `set_bead_inspection_param` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

16.2 OCV

close_ocv (: : OCVHandle :)

Clear an OCV tool.

`close_ocv` closes an open OCV tool and frees the memory. The OCV tool has been created using [create_ocv_proj](#) or [read_ocv](#). The handle is after this call no longer valid.

Parameters

- ▷ **OCVHandle** (input_control) ocv $\leadsto$ *handle*
Handle of the OCV tool which has to be freed.

Example

```

read_ocv("ocv_file",&ocv_handle);
for (i=0; i<1000; i++)
{
    grab_image_async(&Image,fg_handle,-1);
    reduce_domain(Image,ROI,&Pattern);
    do_ocv_simple(Pattern,ocv_handle,"A",
                  "true","true","false","true",10,
                  &Quality);
}
close_ocv(ocv_handle);

```

Result

`close_ocv` returns 2 (`H_MSG_TRUE`), if the handle is valid. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `OCVHandle`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

[close_ocr](#)

Module

OCR/OCV

create_ocv_proj (: : PatternNames : OCVHandle)

Create a new OCV tool based on gray value projections.

`create_ocv_proj` creates a new OCV tool. This tool will be used to train good-patterns for the optical character verification. The training is done using the operator [traind_ocv_proj](#). Thus [traind_ocv_proj](#) is normally called after `create_ocv_proj`.

The pattern comparison is based on the gray projections: For every training pattern the horizontal and vertical gray projections are calculated by summing up the gray values along the rows and columns inside the region of the pattern. This operation is applied to the training patterns and the test patterns. For the training patterns the result is stored inside the OCV tool to save runtime while comparing patterns. The OCV is done by comparing the corresponding projections. The Quality is the similarity of the projections.

Input for `create_ocv_proj` are the names of the patterns ([PatternNames](#)) which have to be trained. The number and the names can be chosen arbitrary. In most case only one pattern will be trained, thus only one name has to be specified. The names will be used when doing the OCV ([do_ocv_simple](#)). It is possible to specify more names than actually used. These might be trained later.

To close the OCV tool, i.e. to free the memory, the operator [close_ocv](#) is called.

Parameters

- ▷ **PatternNames** (input_control) string(-array) $\leadsto$ string
List of names for patterns to be trained.
Default: 'a'
- ▷ **OCVHandle** (output_control) ocv $\leadsto$ handle
Handle of the created OCV tool.

Example

```
create_ocv_proj("A",&ocv_handle);
draw_region(&ROI,window_handle);
reduce_domain(Image,ROI,&Sample);
traind_ocv_proj(Sample,ocv_handle,"A","single");
```

Result

`create_ocv_proj` returns 2 (`H_MSG_TRUE`), if the parameters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Alternatives

[read_ocv](#)

See also

[create_ocr_class_box](#)

Module

OCR/OCV

deserialize_ocv (: : SerializedItemHandle : OCVHandle)

Deserialize a serialized OCV tool.

`deserialize_ocv` deserializes an OCV tool, that was serialized by [serialize_ocv](#) (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The serialized OCV tool is defined by the handle [SerializedItemHandle](#). The deserialized values are stored in an automatically created OCV tool with the handle [OCVHandle](#). After deserializing the tool the training can be completed for those patterns which have not been trained so far. Otherwise, a pattern comparison can be applied directly by calling [do_ocv_simple](#).

Parameters

- ▷ **SerializedItemHandle** (input_control) serialized_item $\leadsto$ handle
Handle of the serialized item.
- ▷ **OCVHandle** (output_control) ocv $\leadsto$ handle
Handle of the OCV tool.

Result

If the parameters are valid, the operator `deserialize_ocv` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors
<code>fread_serialized_item</code> , <code>receive_serialized_item</code> , <code>serialize_ocv</code>
Possible Successors
<code>do_ocv_simple</code> , <code>close_ocv</code>
Module
OCR/OCV

```
do_ocv_simple ( Pattern : : OCVHandle, PatternName, AdaptPos,
                AdaptSize, AdaptAngle, AdaptGray, Threshold : Quality )
```

Verification of a pattern using an OCV tool.

`do_ocv_simple` evaluates the pattern in (`Pattern`). Before the evaluation the good-pattern has to be trained by using the operator `traind_ocv_proj`. Both patterns should have roughly the same (relative) extent and shape. To specify which of the trained patterns is used as reference its name is specified in `PatternName`. The next four parameters influence the automatic adaption: `AdaptPos` and `AdaptSize` refer to the geometry of the pattern. `AdaptPos` specifies whether a shift of the position will be adapted automatically. `AdaptSize` is used to adapt to changes in the size of the pattern. `AdaptAngle` is not implemented. The parameter `AdaptGray` controls the adaption to changes of the gray values. This comprises additive and multiplicative changes of the intensity.

The parameter `Threshold` specifies the minimum difference of the gray values to be treated as an error. In this case the percentage of wrong pixels is returned. If the value is below 0 the sum of all errors normalized with respect to the size is returned.

The result of the operator is the `Quality` of the pattern with a value between 0 and 1. The value 1 corresponds to a pattern with no faults. The value 0 corresponds to a very big fault.

Parameters
▷ Pattern (input_object) singlechannelimage(-array) $\leadsto$ <i>object</i> : byte Characters to be verified. ▷ OCVHandle (input_control) ocv $\leadsto$ <i>handle</i> Handle of the OCV tool. ▷ PatternName (input_control) string(-array) $\leadsto$ <i>string</i> Name of the character. Default: 'a' ▷ AdaptPos (input_control) string $\leadsto$ <i>string</i> Adaption to vertical and horizontal translation. Default: 'true' List of values: <code>AdaptPos</code> $\in$ {'true', 'false'} ▷ AdaptSize (input_control) string $\leadsto$ <i>string</i> Adaption to vertical and horizontal scaling of the size. Default: 'true' List of values: <code>AdaptSize</code> $\in$ {'true', 'false'} ▷ AdaptAngle (input_control) string $\leadsto$ <i>string</i> Adaption to changes of the orientation (not implemented). Default: 'false' List of values: <code>AdaptAngle</code> $\in$ {'false'} ▷ AdaptGray (input_control) string $\leadsto$ <i>string</i> Adaption to additive and scaling gray value changes. Default: 'true' List of values: <code>AdaptGray</code> $\in$ {'true', 'false'} ▷ Threshold (input_control) number $\leadsto$ <i>real</i> Minimum difference between objects. Default: 10 Suggested values: <code>Threshold</code> $\in$ {-1.0, 0.0, 1.0, 5.0, 10.0, 15.0, 20.0, 30.0, 40.0, 50.0, 60.0, 80.0, 100.0, 150.0}

- ▷ **Quality** (output_control)real(-array) $\leadsto$ *real*
 Evaluation of the character.
Value range: $0.0 \leq \text{Quality} \leq 1.0$

Result

`do_ocv_simple` returns 2 (H_MSG_TRUE), if the handle and the characters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`create_ocv_proj`

Module

OCR/OCV

read_ocv (: : FileName : OCVHandle)

Reading an OCV tool from file.

`read_ocv` reads an OCV tool from file. The tool will contain the same information that it contained when saving it with `write_ocv`. After reading the tool the training can be completed for those patterns which have not been trained so far. Otherwise a pattern comparison can be applied directly by calling `do_ocv_simple`.

As extension '.ocv' is used. If this extension is not given with the file name it will be added automatically.

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ *string*
 Name of the file which has to be read.
Default: 'test_ocv'
File extension: .ocv
- ▷ **OCVHandle** (output_control)ocv $\leadsto$ *handle*
 Handle of read OCV tool.

Example

```
read_ocv("ocv_file",&ocv_handle);
for (i=0; i<1000; i++)
{
    grab_image_async(&Image,fg_handle,-1);
    reduce_domain(Image,ROI,&Pattern);
    do_ocv_simple(Pattern,ocv_handle,"A",
                  "true","true","false","true",10,
                  &Quality);
}
close_ocv(ocv_handle);
```

Result

`read_ocv` returns 2 (H_MSG_TRUE), if the file is correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

serialize_ocv (: : OCVHandle : SerializedItemHandle)

Serialize an OCV tool.

`serialize_ocv` serializes the data of an OCV tool (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_ocv` is converted to a serialized item. The OCV tool is defined by the handle `OCVHandle`. The serialized OCV tool is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ocv`.

<i>Parameters</i>	
▷ OCVHandle (input_control) ocv $\leadsto$ handle Handle of the OCV tool.	
▷ SerializedItemHandle (output_control) serialized_item $\leadsto$ handle Handle of the serialized item.	

<i>Result</i>

If the parameters are valid, the operator `serialize_ocv` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

<i>Execution Information</i>	
• Multithreading type: reentrant (runs in parallel with non-exclusive operators). • Multithreading scope: global (may be called from any thread). • Processed without parallelization.

traind_ocv_proj (Pattern : : OCVHandle, Name, Mode :)
--

Training of an OCV tool.

`traind_ocv_proj` trains patterns for an OCV tool that has been created using the operators `create_ocv_proj` or `read_ocv`. For this training one or multiple patterns are provided to the system. Such a pattern consists of an image with a reduced domain (ROI) for the area of the pattern. Note that the pattern should

not only contain foreground pixels (e.g., dark pixels of a character) but also background pixels. This can be implemented e.g., by the smallest surrounding rectangle of the pattern. Without this context an evaluation of the pattern is not possible.

If more than one pattern has to be trained this can be achieved by multiple calls (one for each pattern) or by calling `traind_ocv_proj` once with all patterns and a tuple of the corresponding names. The result will be in both cases the same. However using multiple calls will normally result in a longer execution time than using one call with all patterns.

Parameters

- ▷ **Pattern** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte
Pattern to be trained.
- ▷ **OCVHandle** (input_control) ocv $\leadsto$ *handle*
Handle of the OCV tool to be trained.
- ▷ **Name** (input_control) string(-array) $\leadsto$ *string*
Name(s) of the object(s) to analyze.
Default: 'a'
- ▷ **Mode** (input_control) string $\leadsto$ *string*
Mode for training (only one mode implemented).
Default: 'single'
List of values: Mode $\in$ {'single'}

Example

```
create_ocv_proj ("A", &ocv_handle);
draw_region (&ROI, window_handle);
reduce_domain (Image, ROI, &Sample);
traind_ocv_proj (Sample, ocv_handle, "A", "single");
```

Result

`traind_ocv_proj` returns 2 (H_MSG_TRUE), if the handle and the training pattern(s) are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCVHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

write_ocv (: : OCVHandle, FileName :)

Saving an OCV tool to file.

`write_ocv` writes an OCV tool to file. This can be used to save the result of a training (`traind_ocv_proj`). The whole information contained in the OCV tool is stored in the file. The file can be reloaded afterwards using the operator `read_ocv`.

As file extension '.ocv' is used. If this extension is not given with the file name, it will be added automatically.

Parameters

- ▷ **OCVHandle** (input_control) ocv $\leadsto$ *handle*
Handle of the OCV tool to be written.
- ▷ **FileName** (input_control) filename.write $\leadsto$ *string*
Name of the file where the tool has to be saved.
Default: 'test_ocv'
File extension: .ocv

Result

`write_ocv` returns 2 (H_MSG_TRUE), if the data is correct and the file can be written. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

16.3 Structured Light

This chapter describes operators for using structured light.

Concept of Structured Light

The basic concept behind structured light is the display of known patterns onto a display or projector. The way those patterns appear in the scene after hitting surfaces helps to further analyze the surfaces.

To use structured light, a model must first be created using `create_structured_light_model`. The model type is specified in `ModelType`. Currently, only the model type 'deflectometry' is supported. Deflectometry is the procedure of analyzing the reflections of known patterns from specular or semi-specular surfaces. In such a setup, for every pattern image projected on the screen, a camera image of the reflection is acquired. Deformations of the pattern in the camera image imply a defect on the specular surface.

In the following, the steps that are required to perform defect detection on specular surfaces are described briefly.

Create a structured light model: In the first step, a structured light model is created with

- `create_structured_light_model`

or read with

- `read_structured_light_model`.

Set the model parameters: The different structured light model parameters can then be set with `set_structured_light_model_param` or queried with `get_structured_light_model_param`. The pattern parameters '*pattern_width*', '*pattern_height*', '*pattern_orientation*', and '*pattern_type*' specify along with the stripe parameters '*min_stripe_width*' and '*single_stripe_width*' the specifications of the pattern images to be generated and projected onto the specular surface. Finally, the '*persistence*' parameter can be enabled to debug intermediate results.

Generate the pattern images: The pattern images are to be generated with `gen_structured_light_pattern` after setting all relevant parameters. Please ensure that the output images are as needed in the particular setup.

Project the patterns and acquire the camera images: At this stage, the pattern images are shown on the display and reflected by the specular surface. The respective reflected image is acquired by the camera for each pattern image.

Decode the acquired images: The acquired `CameraImages` can be decoded with `decode_structured_light_pattern`. Upon calling this operator, the correspondence images are created and stored in the model `StructuredLightModel`.

Get the results: Now the decoded '*correspondence_image*', as well as other results can be queried with `get_structured_light_object`. The '*defect_image*' can be generated and queried with `get_structured_light_object`. For more details of the different objects that can be queried, please refer to the operator's documentation.

Further operators

The structured light model offers various other operators that help access and update the various parameters of the model.

The operator `write_structured_light_model` enables writing the structured light model to a file. Please note that previously generated pattern images are not written in this file. A structured light model file can be read using `read_structured_light_model`.

Furthermore, it is possible to serialize and deserialize the structured light model using `serialize_structured_light_model` and `deserialize_structured_light_model`.

Further Information

See also the "Solution Guide Basics" for further details.

<code>clear_structured_light_model (: : StructuredLightModel :)</code>
--

Clear a structured light model and free the allocated memory.

The operator `clear_structured_light_model` deletes a structured light model that was created by `create_structured_light_model`. All memory used by the model is freed. The handle of the model is passed in `StructuredLightModel`. It is invalid after the operator call.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter [Inspection / Structured Light](#).

Parameters

- ▷ **StructuredLightModel** (input_control)structured_light_model(-array) ~> *handle*
Handle of the structured light model.

Result

The operator `clear_structured_light_model` returns the value 2 (H_MSG_TRUE) if a valid handle is passed and the referred structured light model can be freed correctly. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

This operator modifies the state of the following input parameter:

- StructuredLightModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

3D Metrology

```
create_structured_light_model (
    : : ModelType : StructuredLightModel )
```

Create a structured light model.

`create_structured_light_model` creates a new structured light model of type `ModelType`. Currently, only the type 'deflectometry' is supported.

The parameters of the structured light model can be queried with `get_structured_light_model_param` and manipulated by calls to `set_structured_light_model_param`.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter [Inspection / Structured Light](#).

Parameters

- ▷ **ModelType** (input_control) string $\leadsto$ string
The type of the created structured light model.
Default: 'deflectometry'
- ▷ **StructuredLightModel** (output_control) structured_light_model $\leadsto$ handle
Handle for using and accessing the structured light model.

Example

```
* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
```

Result

The operator `create_structured_light_model` returns the value 2 (H_MSG_TRUE) if the structured light model can be allocated correctly. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

```
decode_structured_light_pattern (
    CameraImages : : StructuredLightModel : )
```

Decode the camera images acquired with a structured light setup.

`decode_structured_light_pattern` decodes the camera images `CameraImages` that have been previously acquired with a structured light setup. The correspondence images and other intermediate results that are created by the decoding process are stored in the model `StructuredLightModel` and can be accessed afterwards using the operator `get_structured_light_object`.

In the following, the decoding process is explained in detail:

As mentioned in `gen_structured_light_pattern` the first purpose is to find out whether a pixel is in a region where a light stripe is reflected or where a dark stripe is reflected. To simplify this decision process the normalization images are used and a locally varying threshold is determined that is able to cope with objects of varying reflectance and lighting conditions. During the decoding of the acquired camera images all Gray code images are then compared with the previously calculated threshold. A pixel within the image is classified as bright if its gray value is greater or equal this threshold.

Furthermore, the pattern region is segmented during the decoding process. The segmentation is controlled by the parameter `'min_gray_difference'` (see `set_structured_light_model_param`).

Assuming that n Gray code images have been processed, we get a n -bit binary code for each pixel. From this sequence the row and column coordinates up to `'min_stripe_width'/2` of the monitor can be derived.

If the `StructuredLightModel` is a hybrid system consisting not only of Gray code images but also of phase shift images (see `gen_structured_light_pattern`), the next step is to decode the latter ones. The result is a subpixel-precise correspondence image between the monitor coordinates and the camera coordinates that contains the information which camera pixel observes which monitor pixel.

If the `'pattern_type'` of the `StructuredLightModel` is set to `'single_stripe'`, the first step in the decoding process is to decide which single stripe shed its light on a camera pixel. The Gray code sequence and phase are then used to refine the position within the found single stripe.

In real world setups it may occur that the detected Gray code sequence of a pixel is wrong. This can then lead to values in the correspondence images which represent monitor rows or columns larger than the monitor width and height. To avoid these problems, the last step of the decoding process is to remove these values from the correspondence images.

Parameters

- ▷ **CameraImages** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / uint2
Acquired camera images.
- ▷ **StructuredLightModel** (input_control) structured_light_model $\leadsto$ *handle*
Handle of the structured light model.

Example

```
* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Set the size of the monitor
set_structured_light_model_param (StructuredLightModel, \
    'pattern_width', 1600)
set_structured_light_model_param (StructuredLightModel, \
    'pattern_height', 1200)
* Set the smallest width of the stripes in the pattern
set_structured_light_model_param (StructuredLightModel, \
    'min_stripe_width', 8)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Set the expected black/white contrast in the region of interest
set_structured_light_model_param (StructuredLightModel, \
    'min_gray_difference', 70)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Get the computed correspondences and defects
```

```

get_structured_light_object (CorrespondenceImages, StructuredLightModel, \
                             'correspondence_image')
set_structured_light_model_param (StructuredLightModel, 'derivative_sigma', \
                                   Sigma)
get_structured_light_object (DefectImage, StructuredLightModel, \
                             'defect_image')

```

Result

The operator `decode_structured_light_pattern` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `StructuredLightModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

<code>deserialize_structured_light_model</code> (: : <code>SerializedItemHandle</code> : <code>StructuredLightModel</code>)

Deserialize a structured light model.

`deserialize_structured_light_model` deserializes a structured light model that was serialized by [serialize_structured_light_model](#) (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The serialized structured light model is defined by the handle [SerializedItemHandle](#). The deserialized values are stored in an automatically created structured light model with the handle [StructuredLightModel](#).

Parameters

- ▷ **`SerializedItemHandle`** (input_control) `serialized_item` $\leadsto$ *handle*
Handle of the serialized item.
- ▷ **`StructuredLightModel`** (output_control) `structured_light_model` $\leadsto$ *handle*
Handle of the structured light model.

Example

```

* Deserialize the model
deserialize_structured_light_model (SerializedItemHandle, \
                                    StructuredLightModel)

* Get a previously decoded result
get_structured_light_object (CorrespondenceImages, StructuredLightModel, \
                             'correspondence_image')

```

```
* Decode new camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Get the decoded result
get_structured_light_object (CorrespondenceImagesNew, StructuredLightModel, \
                             'correspondence_image')
```

Result

The operator `deserialize_structured_light_model` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `StructuredLightModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

<pre>gen_structured_light_pattern (: PatternImages : StructuredLightModel :)</pre>

Generate the pattern images to be displayed in a structured light setup.

`gen_structured_light_pattern` generates the pattern images that need to be displayed in a structured light setup. Several parameters such as the width and height of the images, the pattern type and the minimal stripe width need to be set in advance in the model `StructuredLightModel` using `set_structured_light_model_param`. Dependent on the set parameters of the `StructuredLightModel`, the number and the appearance of the pattern images vary.

In general, the pattern images can be divided into four groups of images:

- Normalization images
- Gray code images
- Phase shift images
- Single stripe images

General information about the image types

Normalization images:

Decoding of Gray code images relies upon being able to know whether a pixel is in a region where a light stripe is reflected or where a dark stripe is reflected. To allow a robust decoding even for large variations in the surface reflectance, normalization images are used to simplify the process of identifying light and dark regions. The simplest but in most cases also sufficient approach is to generate one entirely black and one entirely white image. During the decoding of the acquired camera images (see `decode_structured_light_pattern`) all Gray

code images are then compared with the mean of the dark and the bright image and a pixel within the image is classified as bright if its gray value is greater or equal the previously calculated mean.

Another approach is to use the Gray code images as explained in the next section and generate an inverted version of these images. A pixel is then classified as light, if its gray value in the first image is brighter than the gray value of the inverted version.

Gray code images:

Before performing any practical task such as detecting defects, the first step in any structured light measurement process is to find a mapping between the pixel plane of the camera and the pixel plane of the monitor. This can be achieved by displaying a series of images that uniquely encode the rows and columns of the monitor. Since Gray code images have some advantages compared to other pattern types, they are typically used for the encoding. An example of a series of vertical and horizontal Gray code images can be seen in the subsequent figure.

Image series of vertical and horizontal Gray code images as generated by `gen_structured_light_pattern`. The patterns are typically displayed on the monitor from the coarsest pattern to the finest one while the stripe width is halved at each level.

Although using Gray code images is a very simple, yet suitable approach, it comes with certain limitations. One drawback is that often many Gray code images are required to achieve a spatial resolution sufficient for practical applications. However, with increasingly finer resolution of the stripes, a correct decoding becomes harder and harder because of blurring effects introduced by the optics involved in the measurement process. To overcome these limitations, the third group of pattern images (phase shift images) can be generated.

Phase shift images:

Phase shift images usually use periodic patterns such as sine or cosine waves to reconstruct the phase and in combination with Gray code images the correspondences between the monitor and the camera coordinates. To allow a decoding that is robust despite variations in the surface reflectance and has a relaxed noise influence, four phase shift images per orientation (vertical or horizontal) are generated. Each image is a cosine wave with phase shifts of $k\pi/2$, where $k = 0, \dots, 3$.

Image series of vertical and horizontal phase shift images as generated by `gen_structured_light_pattern`.

The main advantage of using phase shift images, is that in contrast to Gray code images subpixel-precise correspondences between the monitor and the camera coordinates can be calculated. Since the images are periodic, the

encoding is unique up to integer multiples of the period length. In order to achieve a unique encoding over the entire image, the combination with the Gray code image is necessary.

Single stripe images:

Single stripe images are dark with one bright stripe. The bright stripe is shifted over the images such that each monitor pixel is contained in exactly one stripe. To decide which bright stripe is reflected in the area observed by a camera pixel, the brightest pixel value within the sequence of single stripe images is chosen during decoding. This allows a decoding that is robust despite variations in the surface reflectance.

Image series of vertical and horizontal single stripe images as generated by `gen_structured_light_pattern` for `'pattern_type'` set to `'single_stripe'`.

The Gray code sequence and phase are then used to refine the position within the found single stripe. Thus, while additional single stripe images are generated, the number of created Gray code images will typically decrease slightly.

Image series of vertical and horizontal Gray code images as generated by `gen_structured_light_pattern` for `'pattern_type'` set to `'single_stripe'`.

Information about the generation of the image types

Generating the normalization images:

As mentioned above, HALCON offers two different kinds of normalization images. By default, the `'normalization'` method is set to `'global'` which results in the generation of an entirely black and an entirely white image. To change the method such that each Gray code is additionally inverted, `set_structured_light_model_param` has to be called using the method `'inverted_pattern'`.

The main advantage of using a global normalization is that the number of images is significantly smaller while simultaneously providing satisfying results. Only in cases of partially specular surfaces, the other method might be more robust and should be chosen if the global normalization leads to wrong decoding results.

Generating the Gray code images:

The size, the number and the appearance of the Gray code images is dependent on the following parameters (see `set_structured_light_model_param`): `'pattern_width'`, `'pattern_height'`, `'min_stripe_width'`, and `'pattern_orientation'`.

The first two parameters determine the size of the generated Gray code images and should usually be set to the size of the monitor that is used to display the pattern images. The parameter `'min_stripe_width'` sets the width (in pixels) of the finest stripe of the pattern images that are generated. Additionally, all three parameters have a major influence on the number of created Gray code images.

Let $'max_stripe_width' = 2^{\lceil \log_2 ('pattern_width') \rceil}$ be the maximum stripe width in vertical direction and

$'max_stripe_width' = 2^{\lceil \log_2 ('pattern_height') \rceil}$ be the maximum stripe width in horizontal direction. Then the number of Gray code images `num_images` with stripes oriented in one of the two directions (either horizontal or vertical) is given by

$$num_images = \lceil \log_2 (2 \cdot max_stripe_width / min_stripe_width) \rceil$$

The parameter `'pattern_orientation'` sets the orientation of the Gray code (and phase shift) images that are generated. By default, images with vertical stripes as well as images with horizontal stripes are created. It is also possible to generate images with stripes having only one of the two directions. However, this is not recommended, because changes in the surface can then only be detected in one direction. Solely, if changes on the surface should be ignored or if defects are to be expected in only one direction, this parameter should be changed using [set_structured_light_model_param](#).

Generating the phase shift images:

Since phase shift images are suitable to overcome the practical limitations of Gray code images their generation is recommended and enabled by default.

In case that the accuracy using Gray code images only is sufficient, the creation of phase shift images can be deactivated using [set_structured_light_model_param](#) by setting the `'pattern_type'` to the value `'gray_code'`.

Generating the single stripe images:

In case that using Gray code and phase shift images only is not robust enough (this might happen, for example, on semi-specular surfaces), the creation of single stripe images can be activated using [set_structured_light_model_param](#) by setting the `'pattern_type'` to the value `'single_stripe'`.

The number and the appearance of the single stripe images depends on the parameter `'single_stripe_width'` which sets the width in pixels (see [set_structured_light_model_param](#)).

While additional single stripe images are generated, the number of created Gray code images will typically decrease slightly. To calculate the number of Gray code images, `'max_stripe_width'` is replaced by `'single_stripe_width'` in the formula above.

The use of these images is described in the introduction to the chapter [Inspection / Structured Light](#).

Parameters

- ▷ **PatternImages** (output_object) (multichannel-)image(-array) $\leadsto$ *object* : byte
Generated pattern images.
- ▷ **StructuredLightModel** (input_control) structured_light_model $\leadsto$ *handle*
Handle of the structured light model.

Example

```
* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Set the size of the monitor
set_structured_light_model_param (StructuredLightModel, \
                                   'pattern_width', 1600)
set_structured_light_model_param (StructuredLightModel, \
                                   'pattern_height', 1200)
* Set the smallest width of the stripes in the pattern
set_structured_light_model_param (StructuredLightModel, \
                                   'min_stripe_width', 8)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
```

Result

The operator `gen_structured_light_pattern` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `StructuredLightModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

<code>get_structured_light_model_param</code> (: : <code>StructuredLightModel</code> , <code>GenParamName</code> : <code>GenParamValue</code>)
--

Query parameters of a structured light model.

The operator `get_structured_light_model_param` is used to query the values of the different parameters of a structured light model (`StructuredLightModel`). The names of the desired parameters are passed in the parameter `GenParamName`, the corresponding values are returned in `GenParamValue`. It is possible to query multiple parameters with a single call to `get_structured_light_model_param`. All parameters which can be manipulated by `set_structured_light_model_param` can be queried. Please refer to the documentation of `set_structured_light_model_param` for an explanation of the individual parameters.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter [Inspection / Structured Light](#).

Parameters

- ▷ **`StructuredLightModel`** (input_control) `structured_light_model` $\leadsto$ *handle*
Handle of the structured light model.
- ▷ **`GenParamName`** (input_control) `attribute.name(-array)` $\leadsto$ *string*
Name of the queried model parameter.
Default: `'min_stripe_width'`
List of values: `GenParamName` $\in$ {`'derivative_sigma'`, `'min_gray_difference'`, `'min_stripe_width'`, `'normalization'`, `'pattern_height'`, `'pattern_orientation'`, `'pattern_type'`, `'pattern_width'`, `'single_stripe_width'`, `'persistence'`}
- ▷ **`GenParamValue`** (output_control) `attribute.value(-array)` $\leadsto$ *integer / real / string*
Value of the queried model parameter.

Example

```
* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Get the default value
```

```

get_structured_light_model_param (StructuredLightModel, \
                                'min_stripe_width', Default)

* Set the value
set_structured_light_model_param (StructuredLightModel, \
                                'min_stripe_width', 64)

* Get the value
get_structured_light_model_param (StructuredLightModel, 'min_stripe_width', \
                                MinStripeWidth)

* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)

* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)

```

Result

The operator `get_structured_light_model_param` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

get_structured_light_object (: Object : StructuredLightModel, ObjectName :)

Get (intermediate) iconic results of a structured light model.

With the operator `get_structured_light_object` you can access and inspect (intermediate) iconic results of a structured light measurement setup that has already been decoded using [decode_structured_light_pattern](#).

On the one hand, this is useful to query the results of the decoding process (*'correspondence_image'*) together with further processed results i.e. the defect image (*'defect_image'*). On the other hand, `get_structured_light_object` is also useful for troubleshooting the decoding process. Note that to collect the intermediate results, the *'persistence'* mode has to be enabled for the [StructuredLightModel](#) (see [set_structured_light_model_param](#)) *before* decoding the model.

Objects that can be accessed without persistence mode enabled:

'correspondence_image': Image that describes the correspondences between the monitor and the camera. If the decoding has been performed in vertical and horizontal direction, both correspondence images are returned in an array. Otherwise, only the image of the appropriate direction is returned.

'pattern_region': Segmented region in which the camera images have been decoded. This region is identical to the domain of the correspondence images.

'defect_image': Image that describes possible defects on the surface which reflects the projected patterns towards the camera. Basically, high gray values in the defect image indicate that the gradients of the correspondence images differ significantly from gradients in the neighborhood.

Objects that can be accessed only when in persistence mode:

If the decoding has been performed in vertical and horizontal direction, images of both directions are returned in an array. Otherwise, only the images of the appropriate direction are returned.

'binarized_image': Images of the Gray code sequence where white and black gray values indicate that the camera pixel observed reflections of white or black regions of the projected patterns. If **'normalization'** was set to **'inverted_pattern'** using `set_structured_light_model_param`, this refers to the first image of an inverted pair.

'decoded_phase_shift_image': Decoded phase shift images containing the phase or angle corresponding to the projected phase images. One phase period covers stripes in the projected pattern of an extent **'min_stripe_width'**.

'decoded_single_stripe_image': Decoded single stripe image computed solely from the single stripe images. The correspondence image is a combination of this image with the Gray code and phase shift images, if **'pattern_type'** is set to **'single_stripe'**.

'gray_code_correspondence_image': Correspondence image computed solely from the Gray code images. If **'pattern_type'** is set to **'gray_code_and_phase_shift'**, the actual correspondence image is a combination of this image with the decoded phase shift images. If **'pattern_type'** is set to **'single_stripe'**, the actual correspondence image is a combination of this image with the decoded phase shift images and the decoded single stripe images.

Parameters

- ▷ **Object** (output_object) (multichannel-)object(-array) $\leadsto$ *object*
Iconic result.
- ▷ **StructuredLightModel** (input_control) structured_light_model $\leadsto$ *handle*
Handle of the structured light model.
- ▷ **ObjectName** (input_control) string(-array) $\leadsto$ *string*
Name of the iconic result to be returned.
Default: **'correspondence_image'**
Suggested values: ObjectName $\in$ {**'correspondence_image'**, **'pattern_region'**,
'decoded_single_stripe_image', **'binarized_image'**, **'decoded_phase_shift_image'**,
'gray_code_correspondence_image', **'defect_image'**}

Example

```
* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Get the computed correspondences and defects
get_structured_light_object (CorrespondenceImages, StructuredLightModel, \
                             'correspondence_image')
set_structured_light_model_param (StructuredLightModel, \
                                   'derivative_sigma', Sigma)
get_structured_light_object (DefectImage, StructuredLightModel, \
                             'defect_image')
```

Result

The operator `get_structured_light_object` returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

See also

[gen_structured_light_pattern](#)

Module

3D Metrology

```
read_structured_light_model (
    : : FileName : StructuredLightModel )
```

Read a structured light model from a file.

`read_structured_light_model` reads the structured light model `StructuredLightModel` that has been stored with `write_structured_light_model`. The default HALCON file extension for the structured light model is 'hslm'.

It can be helpful to write a model after setting all the optimal parameters for a particular setup. The model can be read later to easily regenerate pattern images. The objects already generated in the model before writing it can be also revisited later after reading the model.

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter [Inspection / Structured Light](#).

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ *string*
File name.
File extension: .hslm
- ▷ **StructuredLightModel** (output_control) structured_light_model $\leadsto$ *handle*
Handle of the structured light model.

Example

```
* Read the model
read_structured_light_model ('ExampleModel.hslm', StructuredLightModel)
* Get a previously decoded result
get_structured_light_object (CorrespondenceImages, StructuredLightModel, \
                             'correspondence_image')
* Decode new camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Get the decoded result
get_structured_light_object (CorrespondenceImagesNew, StructuredLightModel, \
                             'correspondence_image')
```

Result

The operator `read_structured_light_model` returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

[create_structured_light_model](#), [clear_structured_light_model](#)

Module

3D Metrology

```
serialize_structured_light_model (
    : : StructuredLightModel : SerializedItemHandle )
```

Serialize a structured light model.

`serialize_structured_light_model` serializes a structured light model (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The structured light model is defined by the handle [StructuredLightModel](#). The serialized structured light model is returned by the handle [SerializedItemHandle](#) and can be deserialized by [deserialize_structured_light_model](#).

Parameters

- ▷ **StructuredLightModel** (input_control) `structured_light_model` ~> *handle*
Handle of the structured light model.
- ▷ **SerializedItemHandle** (output_control) `serialized_item` ~> *handle*
Handle of the serialized item.

Example

```
* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Serialize the model
serialize_structured_light_model (StructuredLightModel, \
                                SerializedItemHandle)
```

Result

The operator `serialize_structured_light_model` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

[clear_structured_light_model](#), [fwrite_serialized_item](#), [send_serialized_item](#),

Module

3D Metrology

```
set_structured_light_model_param ( : : StructuredLightModel,
    GenParamName, GenParamValue : )
```

Set parameters of a structured light model.

The operator `set_structured_light_model_param` is used to manipulate the parameters of a structured light model [StructuredLightModel](#). The current parameter settings can be queried with the operator [get_structured_light_model_param](#).

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter [Inspection / Structured Light](#).

General parameters:

'persistence': Enables (`GenParamValue='true'`) or disables (`GenParamValue='false'`) the *'persistence'* mode of the structured light model. When in persistence mode, the model stores intermediate results of the decoding, which can be inspected later by `get_structured_light_object`.

Note that the model might need significant memory space in this mode. Therefore, we recommend to enable this mode only during the setup and for debugging a structured light model setup.

If *'persistence'* is changed, all results of the model are cleared.

Values: *'true'*, *'false'*, 1, 0

Default: *'false'*

Parameters which influence the appearance of the generated pattern images:

'pattern_width': Sets the width of the pattern images that are generated while calling `gen_structured_light_pattern`. Usually, the value should be set to the width of the monitor that is used to display the pattern images.

The value of *'pattern_width'* has to be larger than the value *'min_stripe_width'/2*. In case that *'pattern_type'* is *'single_stripe'*, it also has to be larger than *'single_stripe_width'/2*.

If *'pattern_width'* is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, `gen_structured_light_pattern` has to be called before decoding the model using `decode_structured_light_pattern`.

Values: integer values larger or equal to 1

Default: 1024

'pattern_height': Sets the height of the pattern images that are generated while calling `gen_structured_light_pattern`. Usually, the value should be set to the height of the monitor that is used to display the pattern images.

The value of *'pattern_height'* has to be larger than the value *'min_stripe_width'/2*. In case that *'pattern_type'* is *'single_stripe'*, it also has to be larger than *'single_stripe_width'/2*.

If *'pattern_height'* is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, `gen_structured_light_pattern` has to be called before decoding the model using `decode_structured_light_pattern`.

Values: integer values larger or equal to 1

Default: 1024

'min_stripe_width': Sets the width (in pixels) of the finest stripe of the pattern images that are generated while calling `gen_structured_light_pattern`.

The value has to be a power of two. Furthermore, it has to be smaller or equal the minimum of the parameters *'pattern_width'* and *'pattern_height'* after rounding both up to their next power of two. In case that *'pattern_type'* is *'single_stripe'*, it also has to be smaller or equal the *'single_stripe_width'*.

If *'min_stripe_width'* is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, `gen_structured_light_pattern` has to be called before decoding the model using `decode_structured_light_pattern`.

Values: integer values larger or equal to 4 and a power of 2

Default: 32

'normalization': Sets the normalization mode of the structured light model. If the parameter is set to *'global'*, `gen_structured_light_pattern` generates two additional pattern images composed of a black and a white image. These images are then used in the decoding process to determine the actual pattern region. If instead, the value *'inverted_pattern'* is chosen, each Gray code image is additionally inverted and the pattern region is segmented iteratively using the Gray code images and their inverted version.

If *'normalization'* is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, `gen_structured_light_pattern` has to be called before decoding the model using `decode_structured_light_pattern`.

Values: *'global'*, *'inverted_pattern'*

Default: *'global'*

'pattern_orientation': Sets the orientation of the pattern images that are generated while calling `gen_structured_light_pattern`. If the parameter is set to *'both'*, pattern images with vertical stripes as well as pattern images with horizontal stripes are created. For *'vertical'* the pattern images consist of vertical stripes only, whereas for *'horizontal'* only horizontal stripes are generated.

If *'pattern_orientation'* is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, [gen_structured_light_pattern](#) has to be called before decoding the model using [decode_structured_light_pattern](#).

Values: *'both'*, *'vertical'*, *'horizontal'*

Default: *'both'*

'pattern_type': Sets the type of the pattern images that are generated while calling [gen_structured_light_pattern](#).

<i>'pattern_type'</i>	Generated Images
<i>'gray_code'</i>	Gray code images
<i>'gray_code_and_phase_shift'</i>	Gray code images and phase shift images
<i>'single_stripe'</i>	Single stripe images, Gray code images and phase shift images

Usually, *'gray_code_and_phase_shift'* leads to more accurate results than *'gray_code'* because the combination between Gray code and phase images yields sub-pixel precise monitor coordinates. *'single_stripe'* can increase robustness in case of only partially specular surfaces.

If *'pattern_type'* is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, [gen_structured_light_pattern](#) has to be called before decoding the model using [decode_structured_light_pattern](#).

Values: *'gray_code_and_phase_shift'*, *'gray_code'*, *'single_stripe'*

Default: *'gray_code_and_phase_shift'*

'single_stripe_width': Sets the width (in pixels) of the single stripe that is generated while calling [gen_structured_light_pattern](#) using the *'pattern_type'* *'single_stripe'*.

The value has to be a power of two and has to be greater or equal *'min_stripe_width'*. Furthermore, it has to be smaller or equal the minimum of the parameters *'pattern_width'* and *'pattern_height'* after rounding both up to their next power of two.

Note that *'single_stripe_width'* can only be set in case that *'pattern_type'* is *'single_stripe'*. When *'pattern_type'* is changed to *'single_stripe'*, *'single_stripe_width'* is set to some power of two roughly halfway between the currently set *'min_stripe_width'* and the minimum of *'pattern_width'* and *'pattern_height'*.

If *'single_stripe_width'* is changed, the model is not decodable anymore and all possibly available results are cleared. Therefore, [gen_structured_light_pattern](#) has to be called before decoding the model using [decode_structured_light_pattern](#).

Values: integer values larger or equal to 4 and a power of 2

Default: power of two roughly halfway between the currently set *'min_stripe_width'* and *'pattern_width'*, *'pattern_height'*

Parameters which influence the segmentation of the pattern region:

'min_gray_difference': Sets the minimum gray value difference for the Gray code images. This value is used within [decode_structured_light_pattern](#) to determine the binarized images. Thereby, for each pixel of the camera images the gray value difference between the lighted and the unlighted case is calculated. If the gray value difference of a pixel is smaller than *'min_gray_difference'*, it is excluded from the domain of the binarized images (see [get_structured_light_object](#)) and thus also from further calculations.

If *'min_gray_difference'* is set to the value 0, the segmented region is identical to the input region of the camera images with the only exception that pixels with a decoding result outside the pattern images are excluded.

Values: integer values larger or equal to 0

Default: 30

Parameters which influence the defect image:

'derivative_sigma': Sets the sigma of the Gaussian (i.e. the amount of smoothing) that is used for the convolution of the correspondence image(s) to calculate the defect image.

Values: float or integer value larger or equal 0.01

Default: 2

Parameters

- ▷ **StructuredLightModel** (input_control) structured_light_model $\leadsto$ *handle*
Handle of the structured light model.
- ▷ **GenParamName** (input_control) attribute.name(-array) $\leadsto$ *string*
Name of the model parameter to be adjusted.
Default: 'min_stripe_width'
List of values: GenParamName $\in$ {'derivative_sigma', 'min_gray_difference', 'min_stripe_width', 'normalization', 'pattern_height', 'pattern_orientation', 'pattern_type', 'pattern_width', 'single_stripe_width', 'persistence'}
- ▷ **GenParamValue** (input_control) attribute.value(-array) $\leadsto$ *integer / real / string*
New value of the model parameter.
Default: 32
Suggested values: GenParamValue $\in$ {0, 0.01, 0.5, 0.7, 1, 1.4, 5, 50.0, 64, 128, 256, 1024, 'true', 'false', 'both', 'vertical', 'horizontal', 'global', 'inverted_pattern', 'gray_code_and_phase_shift', 'gray_code', 'single_stripe'}

Example

```
* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Set the size of the monitor
set_structured_light_model_param (StructuredLightModel, \
                                'pattern_width', 1600)
set_structured_light_model_param (StructuredLightModel, \
                                'pattern_height', 1200)
* Set the smallest width of the stripes in the pattern
set_structured_light_model_param (StructuredLightModel, \
                                'min_stripe_width', 8)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Set the expected black/white contrast in the region of interest
set_structured_light_model_param (StructuredLightModel, \
                                'min_gray_difference', 70)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Get the computed correspondences and defects
get_structured_light_object (CorrespondenceImages, StructuredLightModel, \
                             'correspondence_image')
set_structured_light_model_param (StructuredLightModel, 'derivative_sigma', \
                                Sigma)
get_structured_light_object (DefectImage, StructuredLightModel, \
                             'defect_image')
```

Result

The operator `set_structured_light_model_param` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- StructuredLightModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

[get_structured_light_model_param](#)

Module

3D Metrology

```
write_structured_light_model ( : : StructuredLightModel,
    FileName : )
```

Write a structured light model to a file.

`write_structured_light_model` writes the structured light model [StructuredLightModel](#) to the file given by `FileName`. The default HALCON file extension for the structured light model is 'hslm'. The structured light model can be then read with [read_structured_light_model](#). It should be noted that `write_structured_light_model` does *not* write any previously generated pattern images in the structured light model. In other words, only the parameters of the model and objects that were already generated will be written in the file. The list of structured light objects and how to generate each can be found in [get_structured_light_object](#).

For an explanation of the concept of structured light and its supported applications, see the introduction of chapter [Inspection / Structured Light](#).

Parameters

- ▷ **StructuredLightModel** (input_control) `structured_light_model` $\leadsto$ *handle*
Handle of the structured light model.
 - ▷ **FileName** (input_control) `filename.write` $\leadsto$ *string*
File name.
- File extension:** .hslm

Example

```
* Create the model
create_structured_light_model ('deflectometry', StructuredLightModel)
* Generate the patterns to project
gen_structured_light_pattern (PatternImages, StructuredLightModel)
* Decode the camera images
decode_structured_light_pattern (CameraImages, StructuredLightModel)
* Write the model
write_structured_light_model (StructuredLightModel, 'ExampleModel.hslm')
```

Result

The operator `write_structured_light_model` returns the value 2 (H_MSG_TRUE) if the given parameters are valid. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

16.4 Texture Inspection

This chapter describes the operators for texture inspection.

Concept of the texture inspection model

The texture inspection model enables the inspection of textured surfaces with only having to set few parameters. The algorithm requires images of flawless texture for training. The training process extracts texture features from the training images and trains a texture inspection model that is based on Gaussian Mixture Model (GMM) classifiers. After a successful training, texture images can be compared to the texture inspection model and potential defects can be identified. Texture inspection works on image pyramids. This way, multiple frequency ranges of the texture are analyzed.

It is possible to use multi-channel images in the texture inspection pipeline.

In the following, the steps that are required to perform the texture inspection are described briefly.

Create a texture inspection model: In a first step, a texture inspection model is created with

- `create_texture_inspection_model`

or read with

- `read_texture_inspection_model`.

Add training samples: The operator

- `add_texture_inspection_model_image`

adds sample images to the texture inspection model.

Image of a textured surface that is used to train a texture inspection model.

Images that have been added to the texture inspection model with the help of `add_texture_inspection_model_image` can be viewed with `get_texture_inspection_model_image`. If all or a part of the added images are not needed for the current texture inspection, they can be removed from the model using `remove_texture_inspection_model_image`.

Train a texture inspection model: The texture inspection model is trained with

- `train_texture_inspection_model`.

In the training process an image pyramid is created. For each pyramid level a Gaussian Mixture Model (GMM) is trained and a '*novelty_threshold*' is determined. The '*novelty_threshold*' helps to distinguish between flawless and defective texture. After the training, it is possible to query the novelty thresholds with `get_texture_inspection_model_param`.

Several parameters influence the training. They can be set with

- `set_texture_inspection_model_param.`

We recommend the following proceeding for the training:

- Set initial parameters for the training, if needed:
 - *'patch_normalization'*: Setting this parameter to *'weber'*, the features of the used texture patches are normalized making the texture inspection model more robust against illumination changes. Note, however, that sometimes a normalization might not be desired, e.g., if the brightness is needed to discriminate between flawless and defective parts. In that case, a controlled illumination is absolutely necessary for a successful classification.
 - *'patch_rotational_robustness'*: Setting this parameter to *'true'*, the features of the used texture patches are sorted in a way that is robust against rotational changes. This can be used if it is difficult to train all possible orientations of the textured surface via training samples.
- Train the texture inspection model (using the default parameters): The initial training of the texture inspection model may be very time consuming, depending on the number of training images and their resolution. The following time saving strategies can be considered:
 - Zoom the images: Often, the texture inspection works even better on low resolution images. If it is known that the full resolution of the images is not needed, you can significantly reduce the training time by zooming the images. Zooming the image down by a factor of 2, e.g., reduces the training time by factor 4.
 - Accelerate the training: Another, but more risky strategy is to increase the threshold for the stopping criterion of the classifier optimization by setting the parameter *'gmm_em_threshold'*, e.g., from *0.001* to *0.1*. This leads to shorter training times but also to a possibly less accurate texture inspection model. If this strategy is used, we strongly recommend to reduce *'gmm_em_threshold'* again after most of the parameters have been adjusted.
- Check the result of the training: Use a set of images with defective textures, classify them with the trained texture inspection model and check the results as is described for the step *'Apply the texture inspection model'*. If the results are not satisfying, further parameters can be adjusted for the training. The most important parameters are:
 - *'num_levels'* or *'levels'*: The number of used pyramid levels or the explicitly used pyramid levels. Higher pyramid levels work on coarser texture features. If the texture in your images is very coarse, the lower pyramid levels may not be needed for a successful inspection. Then runtime can be reduced by setting the pyramid levels of interest explicitly with *'levels'*. If for example the *'levels'* are set to *[1,3]*, the training and the texture classification are only performed on the first and third level.
 - *'sensitivity'*: Controls how strict the novelty thresholds are set. This way, the sensitivity to novelties can be adjusted. In general, positive values lead to fewer detected defects and negative values lead to less detected defects.
 - *'novelty_threshold'*: Sets the novelty threshold manually. This can be used for fine tuning if the results of the automatic estimation are not optimal.
- Repeat the training, if needed: If parameters were adjusted, usually the texture inspection model has to be retrained.

Apply the texture inspection model: After successfully training the texture inspection model it can be used to classify textured surfaces. Each test image can be compared to the texture inspection model with

- `apply_texture_inspection_model.`

Test image with defects.

For each test image the operator returns a *'novelty_region'*, which indicates where the image has high deviations to the trained texture samples. The *'novelty_region'* is generated by combining the novelty regions of the different pyramid levels. The novelty regions of adjacent levels in the image pyramid are intersected with each other. This step helps to improve the robustness towards noise within the single pyramid level responses. The intersected novelty regions are then added to the returned *'novelty_region'*. If a pyramid level has no adjacent pyramid level, the region itself is added to the *'novelty_region'*. If, for example, *'num_levels'* is set to 1, no adjacent pyramid level exists and the *'novelty_region'* is the novelty region of the first pyramid level.

For debugging, the parameter *'gen_result_handle'* can be set to *'true'* with [set_texture_inspection_model_param](#). This way, the novelty score images and novelty regions of the individual pyramid levels are stored in a result handle. They can then be read with

- [get_texture_inspection_result_object](#).

In general, the novelty score images describe how well each pixel fits to the texture inspection model that was created within the training process. The novelty regions of the single pyramid levels are then calculated by applying the *'novelty_threshold'* to the corresponding novelty score images.

Inspecting the novelty score images and the novelty regions provides you with hints which kinds of errors are detectable on which pyramid levels. Thus, you can decide whether parameters for the training and the classification should be adjusted, e.g., whether it is reasonable to explicitly select only a subset of pyramid levels using the parameter *'levels'*.

(1)

(2)

The resulting *'novelty_score_image'* (1) and the resulting *'novelty_region'* (2) for the test image above.

Further operators

The functionality of the texture inspection can be altered by various parameters. The parameters can be queried with `get_texture_inspection_model_param` and altered with calls to `set_texture_inspection_model_param`.

It is possible to write a texture inspection model to file with the operator `write_texture_inspection_model`. Thereby, only the texture inspection model is stored. The images which were possibly added can be queried with the help of `get_texture_inspection_model_image` and stored separately by calling `write_object`.

To help reduce the memory required by the texture inspection model, it is possible to delete previously added images from the model with `remove_texture_inspection_model_image`.

Furthermore, it is possible to serialize and deserialize the texture inspection model with `serialize_texture_inspection_model` and `deserialize_texture_inspection_model`.

Glossary

In the following, the most important terms that are used in the context of texture inspection are described:

Training images Images that are used for training.

Test images Images which are compared to the trained texture inspection model.

Patch A collection of neighboring pixels.

Texture feature The pixel values within a patch.

Sample A texture feature that is used for training.

Novelty Score In the test process the texture features of the test images are compared to the texture inspection model and their *novelty score* is calculated. The larger this value, the more probable it is that the individual texture feature does not fit to the texture inspection model.

Novelty Threshold The novelty threshold is determined during the training process. Texture features with a novelty score below the novelty threshold fit to the texture inspection model. Texture features with a higher novelty score do not.

```
add_texture_inspection_model_image (
    Image : : TextureInspectionModel : Indices )
```

Add training images to the texture inspection model.

`add_texture_inspection_model_image` adds training images to the texture inspection model (`TextureInspectionModel`). The domain of the training images is considered in all further calculations. Since the feature extraction considers a certain neighborhood of each pixel, no features can be extracted for pixels at the border of the domain. The border size (*Border*) depends on the '*patch_size*' (`set_texture_inspection_model_param`) and computes to $Border = 'patch_size' / 2 - 1$.

All images which are added to the texture inspection model are used within the training process (see `train_texture_inspection_model` for more information). Furthermore, it is possible to query all of the images passed to the texture inspection model with `get_texture_inspection_model_image`.

Every added image receives an index (`Indices`), which allows the user to generate an assignment between the added images and his image data. By calls of `remove_texture_inspection_model_image`, the index can further be used to delete images from the model that are not needed anymore.

It is possible to add either gray-scale images or multichannel images. However, all of the passed images should have the same number of channels.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / uint2 / real
Image of flawless texture.
- ▷ **TextureInspectionModel** (input_control) texture_inspection_model $\leadsto$ *handle*
Handle of the texture inspection model.
- ▷ **Indices** (output_control) integer(-array) $\leadsto$ *integer*
Indices of the images that have been added to the texture inspection model.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                     Indices)

* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
read_image (TrainImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                               TextureInspectionModel, \
                               TextureInspectionResultID)
```

Result

The operator `add_texture_inspection_model_image` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- TextureInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_texture_inspection_model`, `set_texture_inspection_model_param`,
`get_texture_inspection_model_param`

Possible Successors

`train_texture_inspection_model`, `clear_texture_inspection_model`,
`remove_texture_inspection_model_image`, `get_texture_inspection_model_image`

Module

Matching

```
apply_texture_inspection_model ( Image : NoveltyRegion :
    TextureInspectionModel : TextureInspectionResultID )
```

Inspection of the texture within an image.

The operator `apply_texture_inspection_model` compares `Image` with the trained texture inspection model `TextureInspectionModel`. `Image` can either be a single image or a tuple of images. It is possible to pass either gray-scale or multichannel images. Hereby, the operator expects that the passed `Image` has the same number of channels than the model was trained with. The runtime of the `apply_texture_inspection_model` scales roughly linearly with the number of image channels. However, models using colored images are generally better at detecting colored texture defects.

Pixels that do not fit to the texture inspection model are returned in `NoveltyRegion`. Furthermore, if `'gen_result_handle'` has been set to `'true'` with `set_texture_inspection_model_param`, the operator also returns the result handle `TextureInspectionResultID` with more detailed information on the texture classification. If `'gen_result_handle'` is set to `'false'`, `TextureInspectionResultID` is empty.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

For each pyramid level texture features are extracted and classified with the corresponding GMM classifier. The resulting novelty score is then compared to the novelty threshold of the current pyramid level and classified as defective or not. The defective pixels are collected in a novelty region for each pyramid level. These novelty regions are then combined to the final novelty region returned in `NoveltyRegion`. The novelty regions of adjacent levels in the image pyramid are intersected with each other. This step helps to improve the robustness towards noise within the single pyramid level responses. The intersected novelty regions are then added to the returned `'novelty_region'`. If a pyramid level has no adjacent pyramid level the region itself is added to the `'novelty_region'`. If, for example, `'num_levels'` is set to 1, no adjacent pyramid level exists and the `'novelty_region'` is the novelty region of the first pyramid level.

If `'gen_result_handle'` is set to `'true'`, the result handle `TextureInspectionResultID` contains novelty score images and the resulting novelty regions for each pyramid level.

This information is useful for debugging and fine tuning of the model parameters (e.g., the novelty thresholds) and can be accessed with `get_texture_inspection_result_object`.

Parameters

- ▷ **Image** (input_object) (multichannel-)image-array $\leadsto$ *object* : byte / uint2 / real
Image of the texture to be inspected.
- ▷ **NoveltyRegion** (output_object) region-array $\leadsto$ *object*
Novelty regions.
- ▷ **TextureInspectionModel** (input_control) texture_inspection_model $\leadsto$ *handle*
Handle of the texture inspection model.
- ▷ **TextureInspectionResultID** (output_control) texture_inspection_result $\leadsto$ *handle*
Handle of the inspection results.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Set parameters
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gen_result_handle', 'true')
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                     Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                                TextureInspectionModel, \
                                TextureInspectionResultID)
```

Result

The operator `apply_texture_inspection_model` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators. This operator modifies the state of the following input parameter:

- `TextureInspectionResultID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`train_texture_inspection_model`

Possible Successors

`get_texture_inspection_result_object`, `get_texture_inspection_model_param`,
`clear_texture_inspection_result`, `clear_texture_inspection_model`

Module

Matching

<code>clear_texture_inspection_model</code> (: : <code>TextureInspectionModel</code> :)
--

Clear a texture inspection model and free the allocated memory.

The operator `clear_texture_inspection_model` deletes a texture inspection model that was created by `create_texture_inspection_model`. All memory used by the model is freed. The handle of the model is passed in `TextureInspectionModel`. It is invalid after the operator call.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **`TextureInspectionModel`** (input_control) `texture_inspection_model(-array) ~> handle`
Handle of the texture inspection model.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                   Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                               TextureInspectionModel, \
                               TextureInspectionResultID)
```

Result

The operator `clear_texture_inspection_model` returns the value 2 (`H_MSG_TRUE`) if a valid handle is passed and the referred texture inspection model can be freed correctly. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `TextureInspectionModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

<pre>clear_texture_inspection_result (: : TextureInspectionResultID :)</pre>

Clear a texture inspection result handle and free the allocated memory.

The operator `clear_texture_inspection_result` clears the texture inspection result `TextureInspectionResultID` that was created by [apply_texture_inspection_model](#). All memory used by the model is freed. The handle of the model is invalid after the operator call.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **TextureInspectionResultID** (input_control) `texture_inspection_result(-array) ~> handle`
Handle of the texture inspection results.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)
* Set parameter to generate a result handle
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gen_result_handle', 'true')
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                     Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                                TextureInspectionModel, \
                                TextureInspectionResultID)
```

Result

The operator `clear_texture_inspection_result` returns the value 2 (`H_MSG_TRUE`) if a valid handle is passed and the referred texture inspection model can be freed correctly. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `TextureInspectionResultID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

[apply_texture_inspection_model](#)

Module

Matching

```
create_texture_inspection_model (
    : : ModelType : TextureInspectionModel )
```

Create a texture inspection model.

`create_texture_inspection_model` creates a new texture inspection model of type [ModelType](#). Currently, only the model type 'basic' is supported.

The parameters of the texture inspection can be queried with [get_texture_inspection_model_param](#) and manipulated by calls to [set_texture_inspection_model_param](#).

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **ModelType** (input_control) string $\leadsto$ string
The type of the created texture inspection model.
Default: 'basic'
List of values: `ModelType` $\in$ {'basic'}
- ▷ **TextureInspectionModel** (output_control) texture_inspection_model $\leadsto$ handle
Handle for using and accessing the texture inspection model.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                     Indices)

* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                                TextureInspectionModel, \
                                TextureInspectionResultID)
```

Result

The operator `create_texture_inspection_model` returns the value 2 (`H_MSG_TRUE`) in the texture inspection model can be allocated correctly. Otherwise, an exception will be raised..

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`set_texture_inspection_model_param`, `get_texture_inspection_model_param`,
`add_texture_inspection_model_image`

Module

Matching

deserialize_texture_inspection_model (: : SerializedItemHandle : TextureInspectionModel)
--

Deserialize a serialized texture inspection model.

`deserialize_texture_inspection_model` deserializes a texture inspection model, that was serialized by `serialize_texture_inspection_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized texture inspection model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created texture inspection model with the handle `TextureInspectionModel`.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **SerializedItemHandle** (input_control) serialized_item $\leadsto$ handle
Handle of the serialized item.
- ▷ **TextureInspectionModel** (output_control) texture_inspection_model $\leadsto$ handle
Handle of the texture inspection model.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Set parameters
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gen_result_handle', 'true')
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                     Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Serialize texture inspection model
serialize_texture_inspection_model (TextureInspectionModel, \
                                     SerializedItemHandle)
* Deserialize in Model
```

```

deserialize_texture_inspection_model (SerializedItemHandle, \
                                     TextureInspectionModelSerialized)

* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                               TextureInspectionModelSerialized, \
                               TextureInspectionResultID)

```

Result

If the parameters are valid, the operator `deserialize_texture_inspection_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `TextureInspectionModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

```

get_texture_inspection_model_image (
    : ModelImages : TextureInspectionModel : )

```

Get the training images contained in a texture inspection model.

The operator `get_texture_inspection_model_image` returns all training images contained in a texture inspection model `TextureInspectionModel` that were added by `add_texture_inspection_model_image`.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **ModelImages** (output_object)(multichannel-)image-array $\leadsto$ *object* : byte / uint2
 Training images contained in the texture inspection model.
- ▷ **TextureInspectionModel** (input_control) texture_inspection_model $\leadsto$ *handle*
 Handle of the texture inspection model.

Example

```

* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:

```

```

set_texture_inspection_model_param (TextureInspectionModel, \
                                   'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (ModelImages, TextureInspectionModel, \
                                   Indices)

* Get added training images
get_texture_inspection_model_image (ModelImagesOut, TextureInspectionModel)

```

Result

The operator `get_texture_inspection_model_image` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

`create_texture_inspection_model`, `set_texture_inspection_model_param`,

Module

Matching

```

get_texture_inspection_model_param ( : : TextureInspectionModel,
    GenParamName : GenParamValue )

```

Query parameters of a texture inspection model.

The operator `get_texture_inspection_model_param` is used to query the values of the different parameters of a texture inspection model (`TextureInspectionModel`). The names of the desired parameters are passed in the parameter `GenParamName`, the corresponding values are returned in `GenParamValue`. It is possible to query multiple parameters with a single call to `get_texture_inspection_model_param`. All parameters which can be manipulated by `set_texture_inspection_model_param` can be queried. Please refer to the documentation of `set_texture_inspection_model_param` for an explanation of the individual parameters. It is furthermore possible to query the following parameters:

'gmm_centers': Returns the number of Gaussian distributions which were determined as optimal within the training process. The value can be used as a reference for future texture inspection models. The range of the possible number of distributions is determined by the settings of the parameters `'gmm_pmincenters'` and `'gmm_pmaxcenters'`. Each image pyramid level can have a different number of Gaussian distributions. By adding an index, the number of Gaussian distributions for specific pyramid levels can be queried. For example, `'gmm_centers_3'` returns the number of Gaussian distributions for the third pyramid level.

'image_indices': Returns the indices of the images that have been added to the texture inspection model using `add_texture_inspection_model_image`. Only indices of images are returned that are currently in the texture inspection model and have not been deleted with `remove_texture_inspection_model_image`.

'trained_covartype': Returns the type of covariance matrix that was used during training. The user has the possibility to set the preferred type of covariance matrix by setting `'gmm_covartype'` with `set_texture_inspection_model_param`. However, if the training with the preferred covariance type fails, training is re-initialized with a less strict `'gmm_covartype'`. Hence, if training with `'diag'` fails, a further training with `'spherical'` is attempted.

In order to avoid confusions regarding the returned tuple length, multivalued parameters, such as `'image_indices'`, `'gmm_centers'`, `'levels'` and `'novelty_threshold'` can only be queried alone i.e. without passing any other parameter to `get_texture_inspection_model_param`.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **TextureInspectionModel** (input_control) texture_inspection_model $\leadsto$ *handle*
Handle of the texture inspection model.
- ▷ **GenParamName** (input_control) string(-array) $\leadsto$ *string*
Name of the queried model parameter.
Default: `'novelty_threshold'`
List of values: GenParamName $\in$ {`'num_levels'`, `'levels'`, `'gen_result_handle'`, `'novelty_threshold'`, `'sensitivity'`, `'patch_normalization'`, `'patch_rotational_robustness'`, `'patch_size'`, `'gmm_centers'`, `'gmm_sigma'`, `'gmm_pmincenters'`, `'gmm_pmaxcenters'`, `'gmm_preprocessing'`, `'gmm_ncomp'`, `'gmm_randseed'`, `'gmm_em_max_iter'`, `'gmm_em_threshold'`, `'gmm_em_regularize'`, `'gmm_covartype'`, `'image_indices'`, `'trained_covartype'`}
- ▷ **GenParamValue** (output_control) string(-array) $\leadsto$ *integer / real / string*
Value of the queried model parameter.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                   'gmm_em_max_iter', 1)

* Get parameters
get_texture_inspection_model_param (TextureInspectionModel, 'patch_size', \
                                   PatchSize)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                   Indices)

* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                               TextureInspectionModel, \
                               TextureInspectionResultID)
```

Result

The operator `get_texture_inspection_model_param` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
get_texture_inspection_result_object (
    : Object : TextureInspectionResultID, ResultName : )
```

Query iconic results of a texture inspection.

`get_texture_inspection_result_object` queries the iconic result `ResultName` of the handle `TextureInspectionResultID` returned by `apply_texture_inspection_model`. The result handle `TextureInspectionResultID` was only created when `'gen_result_handle'` was set to `'true'` with `set_texture_inspection_model_param`.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

In the following the possible parameter values for `ResultName` are listed:

'novelty_region': Returns the novelty regions of all pyramid levels in an object tuple. To query the novelty regions of single pyramid levels the corresponding index has to be added, e.g., `'novelty_region_1'`. Please note that if a tuple of images was passed to `apply_texture_inspection_model`, it is only possible to query the novelty regions for the first image within the tuple.

'novelty_score_image': Returns the novelty score images of all pyramid levels in an object tuple. To query the novelty regions of single pyramid levels the corresponding index has to be added, e.g., `'novelty_score_image_1'`. Please note that if a tuple of images was passed to `apply_texture_inspection_model`, it is only possible to query the novelty score images for the first image within the tuple.

Parameters

- ▷ **Object** (output_object)object(-array) $\leadsto$ *object*
Returned iconic object.
- ▷ **TextureInspectionResultID** (input_control)texture_inspection_result $\leadsto$ *handle*
Handle of the texture inspection result.
- ▷ **ResultName** (input_control)string(-array) $\leadsto$ *string / integer*
Name of the iconic object to be returned.
Default: `'novelty_region'`
List of values: `ResultName` $\in$ `{'novelty_score_image', 'novelty_region'}`

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Set parameters
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gen_result_handle', 'true')
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                     Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                                TextureInspectionModel, \
                                TextureInspectionResultID)
```

```
* Get result objects
get_texture_inspection_result_object (Object, TextureInspectionResultID, \
                                     'novelty_score_image')
```

Result

The operator `get_texture_inspection_result_object` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
read_texture_inspection_model (
    : : FileName : TextureInspectionModel )
```

Read a texture inspection model from a file.

`read_texture_inspection_model` reads a texture inspection model that has been stored with [write_texture_inspection_model](#). Since the training of a texture inspection model can consume a relatively long time, the texture inspection model is typically trained in an offline process and written to a file with [write_texture_inspection_model](#). In the online process the texture inspection model is read with `read_texture_inspection_model` and subsequently used for evaluation with [apply_texture_inspection_model](#). The default HALCON file extension for the texture inspection model is 'htim'.

After reading a trained texture inspection model, it is possible to classify test images using [apply_texture_inspection_model](#). However, retraining this model can only be done, if the read model has images. Furthermore, modifying parameters of the model leads to an entire retraining.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ *string*
File name.
File extension: .htim
- ▷ **TextureInspectionModel** (output_control) texture_inspection_model $\leadsto$ *handle*
Handle of the texture inspection model.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)

* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
```

```

Indices)

* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Write out texture inspection model
write_texture_inspection_model (TextureInspectionModel, \
                                'ExampleModel.him')

* Read in Model
read_texture_inspection_model ('ExampleModel.him', \
                                TextureInspectionModelRead)

* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                                TextureInspectionModelRead, \
                                TextureInspectionResultID)

```

Result

If the parameters are valid, the operator `read_texture_inspection_model` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

```

remove_texture_inspection_model_image (
    : : TextureInspectionModel, Indices : RemainingIndices )

```

Clear all or a user-defined subset of the images of a texture inspection model.

`remove_texture_inspection_model_image` clears all or certain selected images that have been stored in a texture inspection model [TextureInspectionModel](#).

On the one hand, the usage of `remove_texture_inspection_model_image` is recommended to reduce the storage space of a saved texture inspection model. This is especially of advantage if the texture inspection model has been trained in an offline process and written with [write_texture_inspection_model](#). In this case, test images can still be classified using [apply_texture_inspection_model](#), while the required storage space is reduced to a minimum. On the other hand, it offers a simple way to delete certain selected images of the texture inspection model that are not needed (anymore) for a subsequent classification process. This allows the user to proceed with an entirely configured model, while only the used image data has to be tuned to solve the underlying inspection problem. Please note that after removing images from the model a retraining is required.

In order to specifically delete images from the texture inspection model, the indices of the respective images have to be specified in the parameter [Indices](#). A validation of all images that are still in the texture inspection model can be made using the value `'image_indices'` in [get_texture_inspection_model_param](#). If the user

still passes unassigned indices to delete images, these indices are ignored. Besides the above mentioned option, `remove_texture_inspection_model_image` also allows to set the parameter `Indices` to the value `'all'`. In this case, all images of the texture inspection model are deleted.

It should be noted that after deleting all images, the model can only be (re)trained, if new images are added using `add_texture_inspection_model_image`. In the case that only a subset of all images has been deleted, a call of `train_texture_inspection_model` requires all steps of the training to be executed, since potentially still available training data does not match the used data.

After calling `remove_texture_inspection_model_image`, the remaining indices of the images that are still in the texture inspection model are returned in the parameter `RemainingIndices`.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **TextureInspectionModel** (input_control) texture_inspection_model(-array) $\leadsto$ *handle*
Handle of the texture inspection model.
- ▷ **Indices** (input_control) integer-array $\leadsto$ *integer*
Indices of the images to be deleted from the texture inspection model.
- ▷ **RemainingIndices** (output_control) integer-array $\leadsto$ *integer*
Indices of the images that remain in the texture inspection model.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                   Indices)
* Get added training images
get_texture_inspection_model_image (TrainImageOut, TextureInspectionModel)
* Remove training images
remove_texture_inspection_model_image (TextureInspectionModel, Indices, \
                                       RemainingIndices)
```

Result

If the parameters are valid, the operator `remove_texture_inspection_model_image` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TextureInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

```
serialize_texture_inspection_model (
    : : TextureInspectionModel : SerializedItemHandle )
```

Serialize a texture inspection model.

`serialize_texture_inspection_model` serializes a texture inspection model (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The texture inspection model is defined by the handle [TextureInspectionModel](#). The serialized texture inspection model is returned by the handle [SerializedItemHandle](#) and can be deserialized by [deserialize_texture_inspection_model](#).

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **TextureInspectionModel** (input_control) texture_inspection_model $\leadsto$ handle
Handle of the texture inspection model.
- ▷ **SerializedItemHandle** (output_control) serialized_item $\leadsto$ handle
Handle of the serialized item.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Set parameters
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gen_result_handle', 'true')
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)
* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                     Indices)
* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Serialize texture inspection model
serialize_texture_inspection_model (TextureInspectionModel, \
                                     SerializedItemHandle)
* Deserialize in Model
deserialize_texture_inspection_model (SerializedItemHandle, \
                                     TextureInspectionModelSerialized)
* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                                TextureInspectionModelSerialized, \
                                TextureInspectionResultID)
```

Result

If the parameters are valid, the operator `serialize_texture_inspection_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

Module

Matching

```
set_texture_inspection_model_param ( : : TextureInspectionModel,  

    GenParamName, GenParamValue : )
```

Set parameters of a texture inspection model.

The operator `set_texture_inspection_model_param` is used to manipulate the parameters of a texture inspection model `TextureInspectionModel`. The current parameter settings can be queried with the operator `get_texture_inspection_model_param`.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

General parameters:

'num_levels': Determines the number of pyramid levels used within the texture inspection process. The number of pyramid levels affects the inspection results as well as the runtime of `train_texture_inspection_model` and `apply_texture_inspection_model`. Per default the number of levels is estimated by the size of the training images. It should be noted, that no more than 5 pyramid levels are used by the estimation process.

Changing this parameter can require a complete new training of the texture inspection model. No retraining is required if the number of levels of a trained texture inspection model are merely reduced.

If the texture in your images is very coarse, the lower pyramid levels may not be needed for a successful inspection. Then you can save a lot of runtime by setting the levels of interest explicitly with *'levels'*.

Values: integer values larger or equal to 1 or *'auto'*

Default: *'auto'*

'levels': Determines the pyramid levels used within the texture inspection process. The number of pyramid levels affects the inspection results as well as the runtime of `train_texture_inspection_model` and `apply_texture_inspection_model`. Per default the pyramid levels are determined by the value of *'num_levels'*. If for example *'num_levels'* is set to four, then the texture inspection is performed for levels 1 to 4. If all available levels should be trained, the value has to be set to *'auto'*.

Changing this parameter can require a complete new training of the texture inspection model. No retraining is required if the number of levels of a trained texture inspection model are merely reduced.

If the texture in your images is very coarse, the lower pyramid levels may not be needed for a successful inspection. Then you can save a lot of runtime by excluding unwanted levels by setting the pyramid levels with *'levels'* explicitly.

In order to avoid confusions regarding the returned tuple length, *'levels'* can only be set alone i.e. without passing any other parameter to `set_texture_inspection_model_param`.

Values: a monotonically increasing tuple of integer values larger or equal to 1, or *'auto'*

Default: *'auto'*

'gen_result_handle': This parameter determines whether or not a result handle is returned by `apply_texture_inspection_model`. If set to *'true'*, the individual pyramid level results can be queried from the texture result handle with `get_texture_inspection_result_object`. This is useful for debugging and fine tuning.

If set to *'false'*, `apply_texture_inspection_model` only returns a novelty region.

Values: *'true'*, *'false'*

Default: *'false'*

Parameters which influence the automatic novelty threshold calculation:

'novelty_threshold': This parameter sets the values of the novelty thresholds, which distinguish between defective and non-defective texture. The novelty thresholds are passed as a tuple and are set for all pyramid levels at once. Therefore, the number of elements must be equal to the number of pyramid levels *'num_levels'*.

Setting the novelty thresholds prior to training has no effect since the training automatically determines novelty thresholds. Hence the novelty thresholds should be adapted after the training. A typical use case is the fine tuning to optimize the results of [apply_texture_inspection_model](#). Please note, if the novelty thresholds have been set explicitly, a new call of [train_texture_inspection_model](#) will re-estimate the novelty thresholds automatically and overwrite any explicitly set novelty thresholds.

It is possible to add an index to set the novelty threshold of a specific pyramid level. For example, *'novelty_threshold_3'* sets the novelty threshold for the third pyramid level.

Values: integer or float values larger or equal to 0 and smaller or equal to 710

Default: Is determined by [train_texture_inspection_model](#)

'sensitivity': This parameter influences the sensitivity of the novelty thresholds which are determined during the training with [train_texture_inspection_model](#). Per default *'sensitivity'* is set to 0.0, which means the novelty thresholds from the training are used directly when calling [apply_texture_inspection_model](#). If a negative value for the parameter *'sensitivity'* is used, the value is added to the novelty boundaries. Hence, a sensitivity value below 0.0 increments the novelty thresholds and therefore leads to potentially fewer detected errors. If instead a positive value is set, the novelty thresholds are decremented which leads to potentially more detected errors.

The automatically determined novelty thresholds can be changed after the training with the parameter *'novelty_threshold'*.

Values: float or integer value

Default: 0.0

Parameters that influence the texture features:

'patch_normalization': Determines the method used to normalize the texture features. A normalization is required if the lighting between different images is not consistent. If set to *'weber'*, the patches are normalized in accordance with the Weber-Fechner law. If the parameter is set to *'none'*, no feature normalization is performed.

Changing this parameter requires a complete new training of the texture inspection model.

Values: *'none'*, *'weber'*

Default: *'none'*

'patch_rotational_robustness': If set to *'true'*, the texture features are sorted in a way to obtain a certain amount of rotational invariance. Sorting the features leads to a loss of feature information and generally makes the texture inspection less sensitive. Also, the runtime is slightly increased. If the parameter is set to *'false'*, the texture features are not sorted.

Alternatively, it is possible to capture all possible rotations within the training images. Increasing the training images leads to an increase of the training time.

Changing this parameter requires a complete new training of the texture inspection model.

Values: *'true'*, *'false'*

Default: *'false'*

'patch_size': This parameter determines the diameter of the extracted texture feature patches in pixels. Higher patch sizes increase the runtime significantly. Therefore this parameter should only be changed with great care. First try to change the image resolution or the number of pyramids used.

Changing this parameter requires a complete new training of the texture inspection model.

Values: odd integer values between 1 and 11

Default: 5

Advanced parameters that influence the GMM classifiers:

Internally, the texture inspection model uses a Gaussian Mixture Model (GMM) classifier. In general, it is recommended not to change the GMM parameters, but for experienced users this is still possible.

Changing these parameters requires a new training of the texture inspection model.

In the following, the parameters which influence the GMM classifiers are described. For more information on classification with GMM classifiers, see [create_class_gmm](#) and [train_class_gmm](#).

- 'gmm_sigma':** This parameter determines the standard deviation of the Gaussian noise which is added to the training samples (see [add_sample_class_gmm](#)).
Values: integer or float values larger or equal to 0.0
Default: 0.0
- 'gmm_pmincenters':** This parameter determines the minimum number of Gaussian distributions per class. **'gmm_pmincenters'** cannot be set to a value larger than the current value of **'gmm_pmaxcenters'**.
Values: integer value larger or equal to 1 and less or equal to **'gmm_pmaxcenters'**
Default: 12
- 'gmm_pmaxcenters':** This parameter determines the maximum number of Gaussian distributions per class. **'gmm_pmaxcenters'** cannot be set to a value smaller than the current value of **'gmm_pmincenters'**.
Values: integer value larger or equal to **'gmm_pmincenters'**
Default: 12
- 'gmm_preprocessing':** This parameter determines the type of preprocessing used to transform the feature vectors.
Values: **'principal_components'**, **'normalization'**, **'none'**
Default: **'normalization'**
- 'gmm_ncomp':** This parameter manipulates the preprocessing in case **'principal_components'** is chosen as the preprocessing method. More specifically, it determines the dimension of the transformed feature vectors. It needs to be chosen such that it is smaller than the feature dimension, which is **'patch_size' × 'patch_size'**. If the **'patch_size'** is changed such that **'patch_size' × 'patch_size' < 'gmm_ncomp'**, the parameter is manipulated accordingly.
Values: integer value larger or equal to 1
Default: 15
- 'gmm_randseed':** This parameter determines the initialization value for the random number generator, which is required to initialize the GMM with random values.
Values: integer value
Default: 42
- 'gmm_em_max_iter':** This parameter determines the maximum number of iterations of the expectation maximization algorithm.
Values: integer values larger or equal to 0
Default: 100
- 'gmm_em_threshold':** This parameter determines the threshold for the relative change of the error for the expectation maximization algorithm to terminate.
Values: integer or float value larger or equal to 0 and smaller than 1.0
Default: 0.001
- 'gmm_em_regularize':** This parameter determines the regularization value for preventing covariance matrix singularity within the training process.
Values: integer or float values larger or equal to 0 and smaller than 1.0
Default: 0.0001
- 'gmm_covartype':** This parameter determines the type of covariance matrix that is used internally.
Values: **'spherical'**, **'diag'**, **'full'**
Default: **'diag'**

Changing the parameters of a trained texture inspection model

If parameters of a texture inspection model are manipulated after a successful call of [train_texture_inspection_model](#), the texture inspection model usually needs to be retrained. Depending on which parameters are changed, different parts of the training need to be recalculated.

A manipulation of the parameters **'gmm_*'** requires a new training of the classifiers. Since a new classifier yields different novelty scores, the novelty thresholds also need to be recalculated. The parameter **'patch_*'** requires a complete new training of the texture inspection model. The parameters **'num_levels'** and **'levels'** require a retraining if the number of levels is increased or levels are set which were not trained beforehand. For example, setting **'levels'** from [1,2,3] to [1,3] does not require a retraining. The operator **'gen_result_handle'** has no effect on a trained texture inspection model and can be manipulated without requiring any retraining.

Parameters

- ▷ **TextureInspectionModel** (input_control) texture_inspection_model $\leadsto$ *handle*
Handle of the texture inspection model.
- ▷ **GenParamName** (input_control) attribute.name(-array) $\leadsto$ *string*
Name of the model parameter to be adjusted.
Default: 'gen_result_handle'
List of values: GenParamName $\in$ {'num_levels', 'levels', 'gen_result_handle', 'novelty_threshold', 'sensitivity', 'patch_normalization', 'patch_rotational_robustness', 'patch_size', 'gmm_sigma', 'gmm_pmincenters', 'gmm_pmaxcenters', 'gmm_preprocessing', 'gmm_ncomp', 'gmm_randseed', 'gmm_em_max_iter', 'gmm_em_threshold', 'gmm_em_regularize', 'gmm_covartype'}
- ▷ **GenParamValue** (input_control) attribute.value(-array) $\leadsto$ *integer / real / string*
New value of the model parameter.
Default: 'true'
List of values: GenParamValue $\in$ {5, 'auto', 'true', 'false', 'none', 'weber', 'principal_components', 'normalization'}

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)

* Set parameters
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gen_result_handle', 'true')

* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                     Indices)

* Train the model
train_texture_inspection_model (TextureInspectionModel)

* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                                TextureInspectionModel, \
                                TextureInspectionResultID)
```

Result

The operator `set_texture_inspection_model_param` returns the value 2 (H_MSG_TRUE) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TextureInspectionModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

train_texture_inspection_model (: : TextureInspectionModel :)

Train a texture inspection model.

`train_texture_inspection_model` trains a texture inspection model with all training images which were added by [add_texture_inspection_model_image](#).

The complete texture inspection process works with image pyramids. The depth of the pyramid is determined by the parameter `'num_levels'` (or `'levels'` if the levels have been set explicitly). In the first step of the training, texture features are extracted and added to the set of training samples for each pyramid level. For each pyramid level a Gaussian Mixture Model (GMM) classifier is determined with all training samples of the corresponding pyramid level. In a third step, the training samples are used to determine a novelty threshold for each pyramid level. In the following, the three training steps are explained in detail:

1. **Feature extraction** extracts a feature for each pixel within the training images. The texture features are calculated according to the settings of the `'patch_*` parameters, which can be manipulated with [set_texture_inspection_model_param](#). Each texture feature is added to the training data of the GMM.
2. **During the training** of the GMMs, the optimal `'gmm_*` parameters are calculated from the training data. The dimension of the single GMMs is determined by the size of the feature patches. Please refer to [set_texture_inspection_model_param](#) for details. For large patch sizes, it can be extremely difficult to obtain a good approximation of the optimal GMM parameters. Also, the run time and memory usage rises significantly. Therefore we recommend to alter the default patch size with care.
More information on GMM classifiers can be found in the description of the operator [create_class_gmm](#).
3. **The calculation of the novelty thresholds** is required to be able to distinguish between defective and non-defective texture. First, the novelty score of each training sample is determined with the GMMs determined in step 2. Then, based on the resulting novelty scores, novelty thresholds are determined for each pyramid level. The automatic determination of the novelty thresholds can be influenced with the parameter `'sensitivity'` that can be set with [set_texture_inspection_model_param](#).

After the training was successful it is possible to classify images with [apply_texture_inspection_model](#). Each pixel is assigned a *novelty score* that is compared to the novelty threshold, which was determined within the third step of the training. For optimal results it is possible to adapt the novelty threshold of the single pyramid levels with [set_texture_inspection_model_param](#).

In general, the manipulation of all parameters, with the exception of `'gen_result_handle'` and `'sensitivity'`, requires a retraining of the texture inspection model. Depending on which part of the training is affected by the corresponding parameter, either the whole training or only single steps have to be recalculated. This can lead to strong variations in the time required for retraining a texture inspection model. A precise description which parameters influence which parts of the algorithm are illustrated in [set_texture_inspection_model_param](#).

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **TextureInspectionModel** (input_control) texture_inspection_model $\leadsto$ handle
Handle of the texture inspection model.

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
```

```

set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                     Indices)

* Train the model
train_texture_inspection_model (TextureInspectionModel)

* Read and apply a test image
read_image (TestImage, 'carpet/carpet_02')
apply_texture_inspection_model (TestImage, DefectCandidates, \
                                TextureInspectionModel, \
                                TextureInspectionResultID)

```

Result

The operator `train_texture_inspection_model` returns the value 2 (`H_MSG_TRUE`) if the given parameters are valid and within acceptable range. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- `TextureInspectionModel`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`add_texture_inspection_model_image`, `set_texture_inspection_model_param`

Possible Successors

`apply_texture_inspection_model`, `clear_texture_inspection_model`,
`remove_texture_inspection_model_image`, `write_texture_inspection_model`,
`serialize_texture_inspection_model`

Module

Matching

<pre> write_texture_inspection_model (: : TextureInspectionModel, FileName :) </pre>

Write a texture inspection model to a file.

`write_texture_inspection_model` writes the texture inspection model `TextureInspectionModel` to the file given by `FileName`. The default HALCON file extension for the texture inspection model is 'htim'. `write_texture_inspection_model` is typically called after the texture inspection model has been trained with `train_texture_inspection_model`. However, it can also be used to save an untrained model. The texture inspection model can be read with `read_texture_inspection_model`. It should be noted that `write_texture_inspection_model` does *not* write any training samples that possibly have been stored in the texture inspection model. Instead, only the currently set parameters of the model, possibly added images and, if trained, the classifiers of the single pyramid levels are written.

For an explanation of the concept of the texture inspection see the introduction of chapter [Inspection / Texture Inspection](#).

Parameters

- ▷ **TextureInspectionModel** (input_control) texture_inspection_model $\leadsto$ *handle*
Handle of the texture inspection model.
- ▷ **FileName** (input_control) filename.write $\leadsto$ *string*
File name.
File extension: .htim

Example

```
* Create texture inspection model
create_texture_inspection_model ('basic', TextureInspectionModel)
* Make this short example fast:
set_texture_inspection_model_param (TextureInspectionModel, \
                                     'gmm_em_max_iter', 1)

* Read and add training images
read_image (TrainImage, 'carpet/carpet_01')
add_texture_inspection_model_image (TrainImage, TextureInspectionModel, \
                                     Indices)

* Train the model
train_texture_inspection_model (TextureInspectionModel)
* Write out texture inspection model
write_texture_inspection_model (TextureInspectionModel, 'ExampleModel.htim')
```

Result

If the parameters are valid, the operator `write_texture_inspection_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

16.5 Variation Model

clear_train_data_variation_model (: : ModelID :)

Free the memory of the training data of a variation model.

`clear_train_data_variation_model` frees the memory of a variation model that was created by [create_variation_model](#). `clear_train_data_variation_model` can be used to reduce the amount of memory required for the variation model (in main memory as well as when writing the model to

file with `write_variation_model`). `clear_train_data_variation_model` can only be called if the model has been prepared for comparison with an image with `prepare_variation_model`. After the call to `clear_train_data_variation_model` the variation model can only be used for image comparison with `compare_variation_model` or `compare_ext_variation_model`. The model cannot be trained any further. Furthermore, the images used for the image comparison can no longer be read with `get_variation_model`. If they are required, `get_variation_model` must be called before `clear_train_data_variation_model` is called.

Parameters

▷ **ModelID** (input_control)variation_model $\leadsto$ handle ID of the variation model.

Result

`clear_train_data_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

compare_ext_variation_model (Image : Region : ModelID, Mode :)

Compare an image to a variation model.

`compare_ext_variation_model` compares the input image `Image` to the variation model given by `ModelID`. `compare_ext_variation_model` is an extension of `compare_variation_model` that provides more modes for the image comparison. Before `compare_ext_variation_model` can be called, the two internal threshold images of the variation model must have been created with `prepare_variation_model` or `prepare_direct_variation_model`. Let $c(x, y)$ denote the input image `Image` and $t_{u,l}$ denote the two threshold images (see `prepare_variation_model` or `prepare_direct_variation_model`). Then, for `Mode` = 'absolute' the output region `Region` contains all points that differ substantially from the model, i.e., the points that fulfill the following condition:

$$c(x, y) > t_u(x, y) \vee c(x, y) < t_l(x, y) .$$

This mode is identical to `compare_variation_model`. For `Mode` = 'light', `Region` contains all points that are too bright:

$$c(x, y) > t_u(x, y) .$$

For `Mode` = 'dark', `Region` contains all points that are too dark:

$$c(x, y) < t_l(x, y) .$$

Finally, for `Mode` = 'light_dark' two regions are returned in `Region`. The first region contains the result of `Mode` = 'light', while the second region contains the result of `Mode` = 'dark'. The respective regions can be selected with `select_objj`.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte / int2 / uint2
Image of the object to be compared.
- ▷ **Region** (output_object) region(-array) $\leadsto$ *object*
Region containing the points that differ substantially from the model.
- ▷ **ModelID** (input_control) variation_model $\leadsto$ *handle*
ID of the variation model.
- ▷ **Mode** (input_control) string $\leadsto$ *string*
Method used for comparing the variation model.
Default: 'absolute'
Suggested values: Mode $\in$ {'absolute', 'light', 'dark', 'light_dark'}

Example

```
read_shape_model ('model.shm', TemplateID)
read_variation_model ('model.var', ModelID)
for K := 1 to 10 by 1
    read_image (Image, 'pen-' + K$'02')
    find_generic_shape_model (Image, TemplateID, MatchResultID, \
                               NumMatchResult)
    get_generic_shape_model_result (MatchResultID, 'all', 'hom_mat_2d', \
                                    HomMat2D)
    dev_display (Image)
    if (NumMatchResult == 1)
```

```

    affine_trans_image (Image, ImageTrans, HomMat2D, 'constant', \
                        'false')
    compare_ext_variation_model (ImageTrans, RegionDiff, ModelID, \
                                'absolute')
    dev_display (RegionDiff)
endif
endfor

```

Result

`compare_ext_variation_model` returns 2 (`H_MSG_TRUE`) if all parameters are correct and if the internal threshold images have been generated with `prepare_variation_model` or `prepare_direct_variation_model`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

Matching

<code>compare_variation_model</code> (Image : Region : ModelID :)
--

Compare an image to a variation model.

`compare_variation_model` compares the input image `Image` to the variation model given by `ModelID`. Before `compare_variation_model` can be called, the two internal threshold images of the variation model must have been created with `prepare_variation_model` or `prepare_direct_variation_model`. Let $c(x, y)$ denote the input image `Image` and $t_{u,l}$ denote the two threshold images (see `prepare_variation_model` or `prepare_direct_variation_model`). Then the output region `Region` contains all points that differ substantially from the model, i.e., the points that fulfill the following condition:

$$c(x, y) > t_u(x, y) \vee c(x, y) < t_l(x, y) .$$

If only too bright or too dark errors should be segmented the operator `compare_ext_variation_model` can be used.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ object : byte / int2 / uint2
Image of the object to be compared.
- ▷ **Region** (output_object) region(-array) $\leadsto$ object
Region containing the points that differ substantially from the model.
- ▷ **ModelID** (input_control) variation_model $\leadsto$ handle
ID of the variation model.

Example

```

read_shape_model ('model.shm', TemplateID)
read_variation_model ('model.var', ModelID)
for K := 1 to 10 by 1
    read_image (Image, 'pen-' + K$'02')
    find_generic_shape_model (Image, TemplateID, MatchResultID, \
                             NumMatchResult)
    get_generic_shape_model_result (MatchResultID, 'all', 'hom_mat_2d', \
                                   HomMat2D)

    dev_display (Image)
    if (NumMatchResult == 1)
        affine_trans_image (Image, ImageTrans, HomMat2D, 'constant', \
                           'false')
        compare_variation_model (ImageTrans, RegionDiff, ModelID)
        dev_display (RegionDiff)
    endif
endfor

```

Result

`compare_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct and if the internal threshold images have been generated with [prepare_variation_model](#) or [prepare_direct_variation_model](#).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

create_variation_model (: : Width, Height, Type,
Mode : ModelID)

Create a variation model for image comparison.

`create_variation_model` creates a variation model that can be used for image comparison. The handle for the variation model is returned in [ModelID](#).

Typically, the variation model is used to discriminate correctly manufactured objects (“good objects”) from incorrectly manufactured objects (“bad objects”). It is assumed that the discrimination can be done solely based on the gray values of the object.

The variation model consists of an ideal image of the object to which the images of the objects to be tested are compared later on with [compare_variation_model](#) or [compare_ext_variation_model](#), and an image that represents the amount of gray value variation at every point of the object. The size of the images with

which the object model is trained and with which the model is compared later on is passed in `Width` and `Height`, respectively. The image type of the images used for training and comparison is passed in `Type`.

The variation model is trained using multiple images of good objects. Therefore, it is essential that the training images show the objects in the same position and rotation. If this cannot be guaranteed by external means, the pose of the object can, for example, be determined by using matching (see `find_generic_shape_model`). The image can then be transformed to a reference pose with `affine_trans_image`.

The parameter `Mode` is used to determine how the image of the ideal object and the corresponding variation image are computed. For `Mode='standard'`, the ideal image of the object is computed as the mean of all training images at the respective image positions. The corresponding variation image is computed as the standard deviation of the training images at the respective image positions. This mode has the advantage that the variation model can be trained iteratively, i.e., as soon as an image of a good object becomes available, it can be trained with `train_variation_model`. The disadvantage of this mode is that great care must be taken to ensure that only images of good objects are trained, because the mean and standard deviation are not robust against outliers, i.e., if an image of a bad object is trained inadvertently, the accuracy of the ideal object image and that of the variation image might be degraded.

If it cannot be avoided that the variation model is trained with some images of objects that can contain errors, `Mode` can be set to `'robust'`. In this mode, the image of the ideal object is computed as the median of all training images at the respective image positions. The corresponding variation image is computed as a suitably scaled median absolute deviation of the training images and the median image at the respective image positions. This mode has the advantage that it is robust against outliers. It has the disadvantage that it cannot be trained iteratively, i.e., all training images must be accumulated using `concat_obj` and be trained with `train_variation_model` in a single call.

In some cases, it is impossible to acquire multiple training images. In this case, a useful variation image cannot be trained from the single training image. To solve this problem, variations of the training image can be created synthetically, e.g., by shifting the training image by ± 1 pixel in the row and column directions or by using gray value morphology (e.g., `gray_erosion_shape` and `gray_dilation_shape`), and then training the synthetically modified images. A different possibility to create the variation model from a single image is to create the model with `Mode='direct'`. In this case, the variation model can only be trained by specifying the ideal image and the variation image directly with `prepare_direct_variation_model`. Since the variation typically is large at the edges of the object, edge operators like `sobel_amp`, `edges_image`, or `gray_range_rect` should be used to create the variation image.

Parameters

- ▷ **Width** (input_control) extent.x $\leadsto$ *integer*
Width of the images to be compared.
Default: 640
Suggested values: Width $\in$ {160, 192, 320, 384, 640, 768}
- ▷ **Height** (input_control) extent.y $\leadsto$ *integer*
Height of the images to be compared.
Default: 480
Suggested values: Height $\in$ {120, 144, 240, 288, 480, 576}
- ▷ **Type** (input_control) string $\leadsto$ *string*
Type of the images to be compared.
Default: 'byte'
Suggested values: Type $\in$ {'byte', 'int2', 'uint2'}
- ▷ **Mode** (input_control) string $\leadsto$ *string*
Method used for computing the variation model.
Default: 'standard'
Suggested values: Mode $\in$ {'standard', 'robust', 'direct'}
- ▷ **ModelID** (output_control) variation_model $\leadsto$ *handle*
ID of the variation model.

Complexity

A variation model created with `create_variation_model` requires $12 * \text{Width} * \text{Height}$ bytes of memory for `Mode = 'standard'` and `Mode = 'robust'` for `Type = 'byte'`. For `Type = 'uint2'` and `Type = 'int2'`, $14 * \text{Width} * \text{Height}$ are required. For `Mode = 'direct'` and after the training data has been cleared with `clear_train_data_variation_model`, $2 * \text{Width} * \text{Height}$ bytes are required for `Type = 'byte'` and $4 * \text{Width} * \text{Height}$ for the other image types.

Result

`create_variation_model` returns 2 (`H_MSG_TRUE`) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

deserialize_variation_model (: : SerializedItemHandle : ModelID)

Deserialize a variation model.

`deserialize_variation_model` deserializes a variation model, that was serialized by [serialize_variation_model](#) (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The serialized variation model is defined by the handle [SerializedItemHandle](#). The deserialized values are stored in an automatically created variation model with the handle [ModelID](#).

Parameters

- ▷ **SerializedItemHandle** (input_control) `serialized_item` $\leadsto$ *handle*
Handle of the serialized item.
- ▷ **ModelID** (output_control) `variation_model` $\leadsto$ *handle*
ID of the variation model.

Result

If the parameters are valid, the operator `deserialize_variation_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_thresh_images_variation_model ( :  MinImage,
                                     MaxImage :  ModelID : )
```

Return the threshold images used for image comparison by a variation model.

`get_thresh_images_variation_model` returns the threshold images of the variation model `ModelID` in `MaxImage` and `MinImage`. The threshold images must be computed with `prepare_variation_model` or `prepare_direct_variation_model` before they can be read out. The formula used for calculating the threshold images is described with `prepare_variation_model` or `prepare_direct_variation_model`. The threshold images are used in `compare_variation_model` and `compare_ext_variation_model` to detect too large deviations of an image with respect to the model. As described with `compare_variation_model` and `compare_ext_variation_model`, gray values outside the interval given by `MinImage` and `MaxImage` are regarded as errors.

Parameters

- ▷ **MinImage** (output_object) image $\leadsto$ object : byte / int2 / uint2
Threshold image for the lower threshold.
- ▷ **MaxImage** (output_object) image $\leadsto$ object : real
Threshold image for the upper threshold.
- ▷ **ModelID** (input_control) variation_model $\leadsto$ handle
ID of the variation model.

Result

`get_thresh_images_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Matching

```
get_variation_model ( :  Image,  VarImage :  ModelID : )
```

Return the images used for image comparison by a variation model.

`get_variation_model` returns the image of the ideal object and the corresponding variation image of the variation model `ModelID` in `Image` and `VarImage`, respectively. The returned images can be used to check whether an image of a bad object has been trained with `train_variation_model`. This can be seen from the variation image. If an image of a bad object has been trained, the variation image typically has large variations in areas that should exhibit no variations.

Parameters

- ▷ **Image** (output_object) image $\leadsto$ object : byte / int2 / uint2
Image of the trained object.
- ▷ **VarImage** (output_object) image $\leadsto$ object : real
Variation image of the trained object.
- ▷ **ModelID** (input_control) variation_model $\leadsto$ handle
ID of the variation model.

Result

`get_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Matching

```
prepare_direct_variation_model ( RefImage,  VarImage :  :  ModelID,
                                AbsThreshold,  VarThreshold :  )
```

Prepare a variation model for comparison with an image.

`prepare_direct_variation_model` prepares a variation model for the image comparison with `compare_variation_model` or `compare_ext_variation_model`. The variation model must have been created with `Mode='direct'` with `create_variation_model`. In contrast to `prepare_variation_model`, the ideal image of the object and the corresponding variation image are not computed with `train_variation_model`, but are specified directly in `RefImage` and `VarImage`. This is useful if the variation model should be created from a single image, as described with `create_variation_model`. The variation image should typically be created with edge operators like `sobel_amp`, `edges_image`, or `gray_range_rect`.

`prepare_direct_variation_model` converts the ideal image `RefImage` and the variation image `VarImage` into two threshold images and stores them in the variation model. These threshold images are used in `compare_variation_model` or `compare_ext_variation_model` to perform the comparison of the current image to the variation model.

Two thresholds are used to compute the threshold images. The parameter `AbsThreshold` determines the minimum amount of gray levels by which the image of the current object must differ from the image of the ideal object. The parameter `VarThreshold` determines a factor relative to the variation image for the minimum difference of the current image and the ideal image. `VarThreshold` utilizes `VarImage` to define regions, in which differences in gray values may occur which should not be counted as errors. This allows variations for specific parts of the object to inspect. `AbsThreshold` and `VarThreshold` each can contain one or two values. If two values are specified, different thresholds can be determined for too bright and too dark pixels. In this mode, the first value refers to too bright pixels, while the second value refers to too dark pixels. If one value is specified, this value refers to both the too bright and too dark pixels. Let $i(x, y)$ be the ideal image `RefImage`, $v(x, y)$ the variation image `VarImage`, $a_u = \text{AbsThreshold}[0]$, $a_l = \text{AbsThreshold}[1]$, $b_u = \text{VarThreshold}[0]$, and $b_l = \text{VarThreshold}[1]$ (or $a_u = \text{AbsThreshold}$, $a_l = \text{AbsThreshold}$, $b_u = \text{VarThreshold}$, and $b_l = \text{VarThreshold}$, respectively). Then the two threshold images $t_{u,l}$ are computed as follows:

$$t_u(x, y) = i(x, y) + \max\{a_u, b_u v(x, y)\} \quad t_l(x, y) = i(x, y) - \max\{a_l, b_l v(x, y)\} .$$

If the current image $c(x, y)$ is compared to the variation model using `compare_variation_model`, the output region contains all points that differ substantially from the model, i.e., that fulfill the following condition:

$$c(x, y) > t_u(x, y) \vee c(x, y) < t_l(x, y) .$$

In `compare_ext_variation_model`, extended comparison modes are available, which return only too bright errors, only too dark errors, or bright and dark errors as separate regions.

After the threshold images have been created they can be read out with `get_thresh_images_variation_model`.

It should be noted that `RefImage` and `VarImage` are not stored as the ideal and variation images in the model to save memory in the model.

Parameters

- ▷ **RefImage** (input_object)singlechannelimage $\leadsto$ object : byte / int2 / uint2
Reference image of the object.
- ▷ **VarImage** (input_object)singlechannelimage $\leadsto$ object : byte / int2 / uint2
Variation image of the object.
- ▷ **ModelID** (input_control)variation_model $\leadsto$ handle
ID of the variation model.
- ▷ **AbsThreshold** (input_control) number(-array) $\leadsto$ real / integer
Absolute minimum threshold for the differences between the image and the variation model.
Default: 10
Suggested values: AbsThreshold $\in$ {0, 5, 10, 15, 20, 30, 40, 50}
Restriction: AbsThreshold $\geq$ 0
- ▷ **VarThreshold** (input_control) number(-array) $\leadsto$ real / integer
Threshold for the differences based on the variation of the variation model.
Default: 2
Suggested values: VarThreshold $\in$ {1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5}
Restriction: VarThreshold $\geq$ 0

Example

```
read_image (Image, 'model')
sobel_amp (Image, VarImage, 'sum_abs', 3)
get_image_pointer1 (Image, Pointer, Type, Width, Height)
create_variation_model (Width, Height, Type, 'direct', ModelID)
prepare_direct_variation_model (Image, VarImage, ModelID, 20, 1)
write_variation_model (ModelID, 'model.var')
```

Result

prepare_direct_variation_model returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

```
prepare_variation_model ( : : ModelID, AbsThreshold,
                          VarThreshold : )
```

Prepare a variation model for comparison with an image.

`prepare_variation_model` prepares a variation model for the image comparison with `compare_variation_model` or `compare_ext_variation_model`. This is done by converting the ideal image and the variation image that have been trained with `train_variation_model` into two threshold images and storing them in the variation model. These threshold images are used in `compare_variation_model` or `compare_ext_variation_model` to speed up the comparison of the current image to the variation model.

Two thresholds are used to compute the threshold images. The parameter `AbsThreshold` determines the minimum amount of gray levels by which the image of the current object must differ from the image of the ideal object. The parameter `VarThreshold` determines a factor relative to the variation image for the minimum difference of the current image and the ideal image. `AbsThreshold` and `VarThreshold` each can contain one or two values. If two values are specified, different thresholds can be determined for too bright and too dark pixels. In this mode, the first value refers to too bright pixels, while the second value refers to too dark pixels. If one value is specified, this value refers to both the too bright and too dark pixels. Let $i(x, y)$ be the ideal image, $v(x, y)$ the variation image, $a_u = \text{AbsThreshold}[0]$, $a_l = \text{AbsThreshold}[1]$, $b_u = \text{VarThreshold}[0]$, and $b_l = \text{VarThreshold}[1]$ (or $a_u = \text{AbsThreshold}$, $a_l = \text{AbsThreshold}$, $b_u = \text{VarThreshold}$, and $b_l = \text{VarThreshold}$, respectively). Then the two threshold images $t_{u,l}$ are computed as follows:

$$t_u(x, y) = i(x, y) + \max\{a_u, b_u v(x, y)\} \quad t_l(x, y) = i(x, y) - \max\{a_l, b_l v(x, y)\} .$$

If the current image $c(x, y)$ is compared to the variation model using `compare_variation_model`, the output region contains all points that differ substantially from the model, i.e., that fulfill the following condition:

$$c(x, y) > t_u(x, y) \vee c(x, y) < t_l(x, y) .$$

In `compare_ext_variation_model`, extended comparison modes are available, which return only too bright errors, only too dark errors, or bright and dark errors as separate regions.

After the threshold images have been created they can be read out with `get_thresh_images_variation_model`. Furthermore, the training data can be deleted with `clear_train_data_variation_model` to save memory.

Parameters

- ▷ **ModelID** (input_control) variation_model $\leadsto$ handle
ID of the variation model.
- ▷ **AbsThreshold** (input_control) number(-array) $\leadsto$ real / integer
Absolute minimum threshold for the differences between the image and the variation model.
Default: 10
Suggested values: `AbsThreshold` $\in$ {0, 5, 10, 15, 20, 30, 40, 50}
Restriction: `AbsThreshold` $\geq$ 0
- ▷ **VarThreshold** (input_control) number(-array) $\leadsto$ real / integer
Threshold for the differences based on the variation of the variation model.
Default: 2
Suggested values: `VarThreshold` $\in$ {1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5}
Restriction: `VarThreshold` $\geq$ 0

Result

`prepare_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ModelID`

read_variation_model (: : FileName : ModelID)
--

Read a variation model from a file.

The operator `read_variation_model` reads a variation model, which has been written with [write_variation_model](#), from the file `FileName`. The default HALCON file extension for a variation model is 'vam'.

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ string
File name.
File extension: .vam
- ▷ **ModelID** (output_control) variation_model $\leadsto$ handle
ID of the variation model.

Result

If the file name is valid, the operator `read_variation_model` returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

serialize_variation_model (: : ModelID : SerializedItemHandle)

Serialize a variation model.

`serialize_variation_model` serializes the data of a variation model (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_variation_model` is converted to a serialized item. The variation model is defined by the handle `ModelID`. The serialized variation model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_variation_model`.

Parameters

- ▷ **ModelID** (input_control)variation_model $\leadsto$ handle ID of the variation model.
- ▷ **SerializedItemHandle** (output_control)serialized_item $\leadsto$ handle Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_variation_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

train_variation_model (Images : : ModelID :)

Train a variation model.

`train_variation_model` trains the variation model that is passed in `ModelID` with one or more images, which are passed in `Images`.

As described for `create_variation_model`, a variation model that has been created using the mode 'standard' can be trained iteratively, i.e., as soon as images of good objects become available, they can be trained with `train_variation_model`. The ideal image of the object is computed as the mean of all previous training images and the images that are passed in `Images`. The corresponding variation image is computed as the standard deviation of the training images and the images that are passed in `Images`.

If the variation model has been created using the mode 'robust', the model cannot be trained iteratively, i.e., all training images must be accumulated using `concat_obj` and be trained with `train_variation_model` in a single call. If any images have been trained previously, the training information of the previous call is discarded. The image of the ideal object is computed as the median of all training images passed in `Images`. The corresponding variation image is computed as a suitably scaled median absolute deviation of the training images and the median image.

Attention

At most 65535 training images can be trained.

Parameters

- ▷ **Images** (input_object)singlechannelimage(-array) $\leadsto$ object : byte / int2 / uint2 Images of the object to be trained.
- ▷ **ModelID** (input_control)variation_model $\leadsto$ handle ID of the variation model.

Example

```

create_variation_model (Width, Height, Type, 'standard', ModelID)
for K := 1 to 10 by 1
    read_image (Image, 'pen-' + K$'02')
    find_generic_shape_model (Image, TemplateID, MatchResultID, \
                             NumMatchResult)
    get_generic_shape_model_result (MatchResultID, 'all', 'hom_mat_2d', \
                                   HomMat2D)
    if (NumMatchResult == 1)
        affine_trans_image (Image, ImageTrans, HomMat2D, 'constant', \
                           'false')
        train_variation_model (ImageTrans, ModelID)
    endif
endfor
prepare_variation_model (ModelID, 10, 4)

```

Result

`train_variation_model` returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Chapter 17

Legacy

17.1 2D Metrology

```
copy_metrology_object ( : : MetrologyHandle,  
                        Index : CopiedIndices )
```

Copy metrology metrology objects of a metrology model.

copy_metrology_object is obsolete and is only provided for reasons of backward compatibility.

`copy_metrology_object` copies metrology metrology objects within this metrology model.

For an explanation of the concept of 2D metrology see the introduction of chapter [2D Metrology](#).

The metrology model is defined by the handle [MetrologyHandle](#). The parameter [Index](#) determines the metrology objects that are copied. With [Index](#) set to 'all', all metrology objects are copied. The operator `copy_metrology_object` returns the index of the new created metrology objects in the parameter [CopiedIndices](#). The order of the new metrology objects corresponds to the order of the original metrology objects. Access to the parameters of the metrology objects of the metrology model is possible, e.g., with the operator [get_metrology_object_param](#).

Parameters

- ▷ **MetrologyHandle** (input_control) metrology_model $\leadsto$ handle
Handle of the metrology model.
- ▷ **Index** (input_control) integer(-array) $\leadsto$ string / integer
Index of the metrology objects.
Default: 'all'
Suggested values: Index $\in$ {'all', 0, 1, 2}
- ▷ **CopiedIndices** (output_control) integer(-array) $\leadsto$ integer
Indices of the copied metrology objects.

Result

If the parameters are valid, the operator `copy_metrology_object` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

```
transform_metrology_object ( : : MetrologyHandle, Index, Row,
                             Column, Phi, Mode : )
```

Transform metrology objects of a metrology model, e.g., for alignment.

transform_metrology_object is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator [align_metrology_model](#) instead.

`transform_metrology_object` translates and rotates the metrology objects contained in [MetrologyHandle](#) specified by the index [Index](#) according to the parameters [Row](#), [Column](#), and [Phi](#).

For an explanation of the concept of 2D metrology see the introduction of chapter [2D Metrology](#).

The index [Index](#) refer to the index returned by the operators [add_metrology_object_circle_measure](#), [add_metrology_object_ellipse_measure](#), [add_metrology_object_line_measure](#), or [add_metrology_object_rectangle2_measure](#). [Index](#) may contain a single value or a tuple of values. If all metrology objects shall be transformed, [Index](#) can be set to *'all'*.

The parameter [Mode](#) can be set to *'absolute'* or *'relative'* and specifies the effect of the transformation:

Mode = 'absolute': The metrology objects are translated to the image coordinates [Row](#) and [Column](#) and rotated by [Phi](#) with respect to the image coordinate system.

For metrology objects of the type ellipse, or rectangle, the origin of the rotation is defined in the center of the metrology object as specified in the operators [add_metrology_object_ellipse_measure](#) or [add_metrology_object_rectangle2_measure](#). For lines and circles, [Phi](#) is ignored.

Mode = 'relative': The values of the transformation are considered as relative values, i.e., they are specified relative to the previous position and rotation of the metrology object.

For metrology objects of the type ellipse, or rectangle, the origin of the rotation is defined in the center of the metrology object as specified in the operators [add_metrology_object_ellipse_measure](#), or [add_metrology_object_rectangle2_measure](#). For lines, the starting point of the line is used as origin of the rotation. For circles, [Phi](#) is ignored.

`transform_metrology_object` is fastest if no rotation is defined, the original and translated measure regions both lie completely within the image. In all other cases, the measure regions have to be newly generated, which is slower.

Attention

Note that any results (fitted geometric shapes) that have been generated by the operator [apply_metrology_model](#) before calling `transform_metrology_object` are discarded during the transformation.

Parameters

- ▷ **MetrologyHandle** (input_control) metrology_model $\leadsto$ handle
Handle of the metrology model.
- ▷ **Index** (input_control) integer(-array) $\leadsto$ string / integer
Index of the metrology objects.
Default: *'all'*
Suggested values: $\text{Index} \in \{\text{'all'}, 0, 1, 2\}$
- ▷ **Row** (input_control) real(-array) $\leadsto$ real / integer
Translation in row direction.
- ▷ **Column** (input_control) real(-array) $\leadsto$ real / integer
Translation in column direction.
- ▷ **Phi** (input_control) real(-array) $\leadsto$ real / integer
Rotation angle.
- ▷ **Mode** (input_control) string(-array) $\leadsto$ string
Mode of the transformation.
Default: *'absolute'*
Suggested values: $\text{Mode} \in \{\text{'absolute'}, \text{'relative'}\}$

Result

If the parameters are valid, the operator `transform_metrology_object` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

2D Metrology

17.2 Classification

clear_sampset (: : SampKey :)
--

Free memory of a data set.

clear_sampset is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

`clear_sampset` frees the memory which was used for training data set having read by `read_sampset`. This memory is only reusable in combination with `read_sampset`.

Parameters

- ▷ **SampKey** (input_control) feature_set $\leadsto$ handle
Number of the data set.

Result

`clear_sampset` returns 2 (H_MSG_TRUE). An exception is raised if the key `SampKey` does not exist.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SampKey

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

create_class_box (: : : ClassifHandle)

Create a new classifier.

create_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

`create_class_box` creates a new adaptive classifier. All operators which are explained in chapter classification refer to such a initialized classifier (of type 2). See `learn_class_box` for more details about the functionality of the classifier.

Parameters

▷ **ClassifHandle** (output_control) class_box $\leadsto$ handle
Handle of the classifier.

Result

`create_class_box` returns 2 (H_MSG_TRUE) if the parameter is correct. An exception is raised if a classifier with this name already exists or there is not enough memory.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

```
descript_class_box ( : : ClassifHandle, Dimensions : ClassIdx,
    BoxIdx, BoxLowerBound, BoxHigherBound, BoxNumSamplesTrain,
    BoxNumSamplesWrong )
```

Describe the classes of a box classifier.

descript_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

`descript_class_box` describes the classes of a box classifier. A box classifier uses a set of hyper cuboids (boxes) for every class. These boxes describe the distribution of the samples.

`descript_class_box` returns for every class ([ClassIdx](#)) the boundaries of every contained box ([BoxIdx](#)) from dimension 1 up to [Dimensions](#) ([BoxLowerBound](#), [BoxHigherBound](#)) as well as the number of samples that were used during the learning phase to determine these boundaries at each dimension ([BoxNumSamplesTrain](#)). Furthermore, the number of samples that were assigned to the wrong class during the learning phase is returned in [BoxNumSamplesWrong](#).

The boundary information of the boxes can be used to inspect the box classifier.

Parameters

- ▷ **ClassifHandle** (input_control) [class_box](#) ~> *handle*
Handle of the classifier.
- ▷ **Dimensions** (input_control) [integer](#) ~> *integer*
Highest dimension for output.
Default: 3
- ▷ **ClassIdx** (output_control) [integer\(-array\)](#) ~> *integer*
Indices of the classes.
- ▷ **BoxIdx** (output_control) [integer\(-array\)](#) ~> *integer*
Indices of the boxes.
- ▷ **BoxLowerBound** (output_control) [integer\(-array\)](#) ~> *integer*
Lower bounds of the boxes (for each dimension).
- ▷ **BoxHigherBound** (output_control) [integer\(-array\)](#) ~> *integer*
Higher bounds of the boxes (for each dimension).
- ▷ **BoxNumSamplesTrain** (output_control) [integer\(-array\)](#) ~> *integer*
Number of training samples that were used to define this box (for each dimension).
- ▷ **BoxNumSamplesWrong** (output_control) [integer\(-array\)](#) ~> *integer*
Number of training samples that were assigned incorrectly to the box.

Result

`descript_class_box` returns 2 ([H_MSG_TRUE](#)).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[create_class_box](#), [learn_class_box](#), [set_class_box_param](#)

Possible Successors

[enquire_class_box](#), [learn_class_box](#), [write_class_box](#), [close_class_box](#)

[write_class_box](#)

Module

Foundation

```
deserialize_class_box ( : : ClassifHandle,
SerializedItemHandle : )
```

Deserialize a serialized classifier.

deserialize_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

`deserialize_class_box` deserializes a classifier, that was serialized by `serialize_class_box` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized classifier is defined by the handle `SerializedItemHandle`. The values of the current classifier, defined by the handle `ClassifHandle`, are overwritten.

Attention

All values of the classifier are going to be overwritten.

Parameters

- ▷ **ClassifHandle** (input_control) `class_box` $\leadsto$ *handle*
Handle of the classifier.
- ▷ **SerializedItemHandle** (input_control) `serialized_item` $\leadsto$ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `deserialize_class_box` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`fread_serialized_item`, `receive_serialized_item`, `serialize_class_box`,
`create_class_box`

Possible Successors

`test_sampset_box`, `enquire_class_box`, `write_class_box`, `close_class_box`,
`clear_sampset`

`create_class_box`, `serialize_class_box`

Module

Foundation

```
enquire_class_box ( : : ClassifHandle, FeatureList : Class )
```

Classify a tuple of attributes.

enquire_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

`FeatureList` is a tuple of any floating point- or integer numbers (attributes) which has to be assigned to a class with assistance of a previous trained (`learn_class_box`) classifier. It is possible to specify attributes as unknown by indicating the symbol '*' instead of a number. If you specify `n` values, then all following values, i.e. the attributes `n+1` until 'max', are automatically supposed to be undefined.

See `learn_class_box` for more details about the functionality of the classifier.

You may call the operators [learn_class_box](#) and [enquire_class_box](#) alternately, so that it is possible to classify already in the phase of learning. This means you could see when a satisfying behavior had been reached.

Parameters

- ▷ **ClassifHandle** (input_control) class_box $\leadsto$ handle
Handle of the classifier.
- ▷ **FeatureList** (input_control) real-array $\leadsto$ real / integer / string
Array of attributes which has to be classified.
Default: 1.0
- ▷ **Class** (output_control) integer $\leadsto$ integer
Number of the class to which the array of attributes had been assigned.

Result

[enquire_class_box](#) returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[create_class_box](#), [learn_class_box](#), [set_class_box_param](#)

Possible Successors

[learn_class_box](#), [write_class_box](#), [close_class_box](#)

Alternatives

Module

Foundation

```
enquire_reject_class_box ( : : ClassifHandle,
    FeatureList : Class )
```

Classify a tuple of attributes with rejection class.

[enquire_reject_class_box](#) is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

[FeatureList](#) is a tuple of any floating point- or integer numbers (attributes) which has to be assigned to a class with assistance of a previous trained ([learn_class_box](#)) classifier. It is possible to specify attributes as unknown by indicating the symbol '*' instead of a number. If you specify n values, then all following values, i.e. the attributes n+1 until 'max', are automatically supposed to be undefined.

If the array of attributes cannot be assigned to a class, i.e. the array does not reside inside of one of the hyper boxes, then in contrary to [enquire_class_box](#) not the next class is going to be returned, but the rejection class -1 as a result is going to be passed.

See [learn_class_box](#) for more details about the functionality of the classifier.

You may call the operators [learn_class_box](#) and [enquire_class_box](#) alternately, so that it is possible to classify already in the phase of learning. By this means you could see when a satisfying behavior had been reached.

Parameters

- ▷ **ClassifHandle** (input_control) class_box $\leadsto$ handle
Handle of the classifier.
- ▷ **FeatureList** (input_control) real-array $\leadsto$ real / integer / string
Array of attributes which has to be classified.
Default: 1.0

- ▷ **Class** (output_control)integer $\leadsto$ integer
Number of the class, to which the array of attributes had been assigned or -1 for the rejection class.

Result

enquire_reject_class_box returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_class_box_param (: : ClassifHandle, Flag : Value)

Get information about the current parameter.

get_class_box_param is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

[get_class_box_param](#) gets the parameter of the classifier. The meaning of the parameter is explained in [set_class_box_param](#).

Default values: 'min_samples_for_split' = 80, 'split_error' = 0.1, 'prop_constant' = 0.25.

Parameters

- ▷ **ClassifHandle** (input_control) class_box $\leadsto$ handle
Handle of the classifier.
- ▷ **Flag** (input_control) string $\leadsto$ string
Name of the system parameter.
Default: 'split_error'
List of values: Flag $\in$ {'split_error', 'prop_constant', 'used_memory', 'min_samples_for_split'}
- ▷ **Value** (output_control) number $\leadsto$ real / integer
Value of the system parameter.

Result

[get_class_box_param](#) returns 2 (H_MSG_TRUE). An exception is raised if [Flag](#) has been set with wrong values.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`create_class_box`, `set_class_box_param`

Module

Foundation

```
learn_class_box ( : : ClassifHandle, Features, Class : )
```

Train the classifier.

learn_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

Features is a tuple of any floating point numbers or integers (attributes) which has to be assigned to the class **Class**. This class is specified by an integer. You may use the operator `enquire_class_box` later to find the most probable class for any array (=tuple). The algorithm tries to describe the set of arrays of one class by hyper cuboids in the feature space. On demand you may even create several cuboids per class. Hence it is possible to learn disjunct concepts, too. I.e. such concepts which split in several “cluster” of points in the feature space. The data structure is hidden to the user and only accessible with such operators which are described in this chapter.

Note that if a class consists of disjunct sub-classes that would lead to a splitting of the respective hyper cuboid, the training samples should be in random order with respect to the sub-classes. Otherwise, the splitting of the hyper cuboid will be sub-optimal.

It is possible to specify attributes as unknown by indicating the symbol '*' instead of a number. If you specify n values, then all following values, i.e. the attributes n+1 until 'max', are automatically supposed to be undefined.

You may call the operators `learn_class_box` and `enquire_class_box` alternately, so that it is possible to classify already in the phase of learning. By this means you could see when a satisfying behavior had been reached.

The classifier is going to be bigger using further training. This means, that it is not advisable to continue training after reaching a satisfactory behavior.

Parameters

- ▷ **ClassifHandle** (input_control) class_box $\leadsto$ handle
Handle of the classifier.
- ▷ **Features** (input_control) number-array $\leadsto$ real / integer / string
Array of attributes to learn.
Default: [1.0,1.5,2.0]
- ▷ **Class** (input_control) integer $\leadsto$ integer
Class to which the array has to be assigned.
Default: 1

Result

`learn_class_box` returns 2 (H_MSG_TRUE) for a normal case. An exception is raised if there are memory allocation problems. The number of classes is constrained. If this limit is passed, an exception is raised, too.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

Foundation

```
learn_sampset_box ( : : ClassifHandle, SampKey, Outfile, NSamples,
                    StopError, ErrorN : )
```

Train the classifier with one data set.

learn_sampset_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

[learn_sampset_box](#) trains the classifier with data for the key [SampKey](#) (see [read_sampset](#)). The training sequence is terminated at least after [NSamples](#) examples. If [NSamples](#) is bigger than the number of examples in [SampKey](#), then a cyclic start at the beginning occurs. If the error underpasses the value [StopError](#), then the training sequence is prematurely terminated. [StopError](#) is calculated with N / ErrorN . Whereby N means the number of examples which were wrong classified during the last [ErrorN](#) training examples. Typically [ErrorN](#) is the number of examples in [SampKey](#) and [NSamples](#) is a multiple of it. If you want a data set with 100 examples to run 5 times at most and if you want it to terminate with an error lower than 5%, then the corresponding values are [NSamples](#) = 500, [ErrorN](#) = 100 and [StopError](#) = 0.05. A protocol of the training activity is going to be written in file [Outfile](#).

Parameters

- ▷ **ClassifHandle** (input_control) [class_box](#) $\rightsquigarrow$ *handle*
Handle of the classifier.
- ▷ **SampKey** (input_control) [feature_set](#) $\rightsquigarrow$ *handle*
Number of the data set to train.
- ▷ **Outfile** (input_control) [filename.write](#) $\rightsquigarrow$ *string*
Name of the protocol file.
Default: 'training_prot'
- ▷ **NSamples** (input_control) [integer](#) $\rightsquigarrow$ *integer*
Number of arrays of attributes to learn.
Default: 500
- ▷ **StopError** (input_control) [real](#) $\rightsquigarrow$ *real*
Classification error for termination.
Default: 0.05
- ▷ **ErrorN** (input_control) [integer](#) $\rightsquigarrow$ *integer*
Error during the assignment.
Default: 100

Result

[learn_sampset_box](#) returns 2 ([H_MSG_TRUE](#)). An exception is raised if key [SampKey](#) does not exist or there are problems while opening the file.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

read_class_box (: : ClassifHandle, FileName :)

Read a classifier from a file.

read_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

`read_class_box` reads the saved classifier from the file `FileName` (see [write_class_box](#)). The values of the current classifier are overwritten. The default HALCON file extension for the box classifier is 'gbc'.

Attention

All values of the classifier are going to be overwritten.

Parameters

- ▷ **ClassifHandle** (input_control) class_box $\leadsto$ handle
Handle of the classifier.
- ▷ **FileName** (input_control) filename.read $\leadsto$ string
Filename of the classifier.
File extension: .gbc

Result

`read_class_box` returns 2 (H_MSG_TRUE). An exception is raised if it was not possible to open file `FileName` or the file has the wrong format.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

read_sampset (: : FileName : SampKey)

Read a training data set from a file.

read_sampset is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

The training examples are accessible with the key [SampKey](#) by calling the operators [clear_sampset](#) and [learn_sampset_box](#). You may edit the file using an editor. Every row contains an array of attributes with corresponding class. An example for a format might be:

(1.0, 25.3, *, 17 | 3)

This row specifies an array of attributes which belong to class 3. In this array the third attribute is unknown. Attributes upwards 5 are supposed to be unknown, too. You may insert comments like `/* .. */` in any place.

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ string
Filename of the data set to train.
Default: 'sampset1'
- ▷ **SampKey** (output_control) feature_set $\leadsto$ handle
Identification of the data set to train.

Result

`read_sampset` returns 2 (H_MSG_TRUE). An exception is raised if it is not possible to open the file or it contains syntax errors or there is not enough memory.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

[test_sampset_box](#), [clear_sampset](#), [learn_sampset_box](#)

Module

Foundation

serialize_class_box (: : ClassifHandle : SerializedItemHandle)

Serialize a classifier.

serialize_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

`serialize_class_box` serializes a classifier (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The same data that is written in a file by [write_class_box](#) is converted to a serialized item. The classifier is defined by the handle [ClassifHandle](#). The serialized classifier is returned by the handle [SerializedItemHandle](#) and can be deserialized by [deserialize_class_box](#).

Parameters

- ▷ **ClassifHandle** (input_control) `class_box` $\leadsto$ *handle*
Handle of the classifier.
- ▷ **SerializedItemHandle** (output_control) `serialized_item` $\leadsto$ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_class_box` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[create_class_box](#), [enquire_class_box](#), [learn_class_box](#), [test_sampset_box](#)

Possible Successors

[fwrite_serialized_item](#), [send_serialized_item](#), [deserialize_class_box](#)

See also

[create_class_box](#), [deserialize_class_box](#)

Module

Foundation

```
set_class_box_param ( : : ClassifHandle, Flag, Value : )
```

Set system parameters for classification.

`set_class_box_param` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

`set_class_box_param` modifies parameter which manipulate the training sequence while calling [learn_class_box](#). Only parameters of the classifier are modified, all other classifiers remain unmodified. `'min_samples_for_split'` is the number of examples at least which have to train in one cuboid of this classifier, before the cuboid is allowed to divide itself. `'split_error'` indicates the critical error. By its exceeding the cuboid divides itself, if there are more than `'min_samples_for_split'` examples to train. `'prop_constant'` manipulates the extension of the cuboids. It is proportional to the average distance of the training examples in this cuboid to the center of the cuboid. More detailed:

$$\text{extension} \times \text{prop} = \text{average distance of the expectation value.}$$

This relation is valid in every dimension. Hence inside a cuboid the dimensions of the feature space are supposed to be independent.

The parameters are set with problem independent default values, which must not modified without any reason. Parameters are only important during a learning sequence. They do not influence on the behavior of [enquire_class_box](#).

Default values:

`'min_samples_for_split' = 80,`

`'split_error' = 0.1,`

`'prop_constant' = 0.25.`

Parameters

- ▷ **ClassifHandle** (input_control) class_box $\leadsto$ handle
Handle of the classifier.
- ▷ **Flag** (input_control) string $\leadsto$ string
Name of the wanted parameter.
Default: 'split_error'
Suggested values: Flag $\in$ { 'min_samples_for_split', 'split_error', 'prop_constant' }
- ▷ **Value** (input_control) number $\leadsto$ real / integer
Value of the parameter.
Default: 0.1

Result

`read_sampset` returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

Foundation

test_sampset_box (: : ClassifHandle, SampKey : Error)

Classify a set of arrays.

test_sampset_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

In contrast to `learn_sampset_box` there is not a learning here. Typically you use `test_sampset_box` to classify independent test data. **Error** gives you information about the applicability of the learned training set on new examples.

Parameters

- ▷ **ClassifHandle** (input_control) class_box $\leadsto$ handle
Handle of the classifier.
- ▷ **SampKey** (input_control) feature_set $\leadsto$ handle
Key of the test data.
- ▷ **Error** (output_control) real $\leadsto$ real
Error during the assignment.

Result

`test_sampset_box` returns 2 (H_MSG_TRUE). An exception is raised, if if key `SampKey` does not exist or problems occur while opening the file.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

write_class_box (: : ClassifHandle , FileName :)

Save a classifier in a file.

write_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM, KNN or GMM operators instead.

[write_class_box](#) writes the classifier [ClassifHandle](#) to the file given by [FileName](#). The classifier can be read with [read_class_box](#). The default HALCON file extension for the box classifier is 'gbc'.

Attention

If a file with this name exists, it is overwritten without a warning. The file can not be edited.

Parameters

- ▷ **ClassifHandle** (input_control) [class_box](#) $\leadsto$ *handle*
Handle of the classifier.
 - ▷ **FileName** (input_control) [filename.write](#) $\leadsto$ *string*
Name of the file which contains the written data.
- File extension:** .gbc

Result

[write_class_box](#) returns 2 (H_MSG_TRUE). An exception is raised if it was not possible to open file [FileName](#).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

17.3 Control

```
ifelse ( : : Condition : )
```

Conditional statement with alternative.

ifelse is obsolete and is only provided for reasons of backward compatibility. **if** should be used instead.

ifelse is a conditional statement with an alternative. If the condition is true (i.e., not 0), all expressions and calls between the head and operator **else** are performed. If the condition is false (i.e., 0) the part between **else** and **endif** is executed. Note that the operator is called **ifelse** and it is displayed as **if** in the program text area.

Parameters

▷ **Condition** (input_control) integer $\leadsto$ integer
Condition for the if statement.

Default: 1

Result

If the condition is correct **ifelse** (as operator) returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Alternatives

if

17.4 DL Classification

The workflow and operators described in this chapter are obsolete and only provided for reasons backward compatibility. New applications should use the workflow and operators described in [Deep Learning / Classification](#).

This chapter explains how to use classification based on deep learning, both for the training and inference phases.

General Workflow

This section describes the main steps and the workflow for classification with Deep Learning using the obsolete workflow.

Prepare the Network and the Data This part is about how to prepare and preprocess your data.

1. First, a pretrained network has to be read using the operator

- **read_dl_classifier**.

This operator is used as well when you want to read your own trained networks, after you saved them with **write_dl_classifier**.

2. To read the data for your deep learning classification training the procedure

- **read_dl_classifier_data_set**

is available. Using this procedure you can get a list of image file paths and their respective labels (the ground truth labels) as well as a list of the unique classes, to which at least one of the listed images belongs.

3. The network will impose several requirements on the images, as the image dimensions and the gray value range. The default values are listed in **read_dl_classifier**. These are the values with which the networks have been pretrained. The network architectures allow different image dimensions, which can be set with **set_dl_classifier_param**, but depending on the network a change may make a retraining necessary. The actually set values can be retrieved with

- `get_dl_classifier_param`.

The procedure `preprocess_dl_classifier_images` provides great guidance on how to implement such a preprocessing stage. We recommend to preprocess and store all images used for the training before starting the classifier training, since this speeds up the training significantly.

4. Next, we recommend to split the dataset into three distinct datasets which are used for training, validation, and testing, see the section “Data” in the chapter [Deep Learning](#). This can be achieved using the procedure

- `split_dl_classifier_data_set`.

5. You need to specify the ‘classes’ (determined before by use of `read_dl_classifier_data_set`) you want to differentiate with your classifier. For this, the operator

- `set_dl_classifier_param`

is available.

This operator can also be used to set hyperparameters, which are important for training, e.g., ‘batch_size’ and ‘learning_rate’. For a more detailed explanation, see the chapter [Deep Learning](#) and the documentation of `set_dl_classifier_param`.

Train the Network and Evaluate the Training Progress Once your network is set up and your data prepared it is time to train the classifier for your specific task.

1. Set the hyperparameters used for training with the operator

- `set_dl_classifier_param`.

For an overview of possible hyperparameters, see the documentation of `set_dl_classifier_param`. Additional explanations can be found in the chapter [Deep Learning](#).

2. To train the classifier the operator

- `train_dl_classifier_batch`

is available. The intermediate training results are stored in the output handle.

As the name of `train_dl_classifier_batch` indicates, this operator processes a batch of data (images and ground truth labels) at once. We iterate through our training data in order to train the classifier successively with `train_dl_classifier_batch`. You can repeat this process multiple times and iterate over so many training epochs until you are satisfied with the training result.

3. To know how well the classifier learns the new task, the procedure

- `plot_dl_classifier_training_progress`

is provided. With it you can plot the classification errors during training. To compute the input necessary for the visualization, the procedures

- `select_percentage_dl_classifier_data`,
- `apply_dl_classifier_batchwise`, and
- `evaluate_dl_classifier`

are available. With them you can reduce the number of images used for this classification validation, apply the classifier on the selected data and compute, for example, the top-1 error.

Apply and Evaluate the Final Classifier Your classifier is trained for your task and ready to be applied. But before deploying in the real world you should evaluate how well the classifier performs on basis of your test data.

1. To apply the classifier on a set containing an arbitrary number of images, use the operator

- `apply_dl_classifier`.

The runtime of this operator depends on the number of batches needed for the given image set.

The results are returned in a handle.

To retrieve the predicted classes and confidences, use the operator

- `get_dl_classifier_result`.

2. Now it is time to evaluate these results. The performance of the classifier can be evaluated as during the training with `evaluate_dl_classifier`.

To visualize and analyze the classifier quality, the confusion matrix is a useful tool (see below for an explanation). For this, you can use the procedures

- `gen_confusion_matrix`
- `gen_interactive_confusion_matrix`.

The interactive procedure gives you the possibility to select examples of a specific category, but it does not work with exported code.

Additionally, after applying the classifier on a set of data, you can use the procedure

- `get_dl_classifier_image_results`

to display and return images according to certain criteria, e.g., wrongly classified ones. Then, you might want to use this input for the procedure

- `dev_display_dl_classifier_heatmap`,

to display a heatmap of the input image, with which you can analyze which regions of the image are relevant for the classification result.

Inference Phase When your classifier is trained and you are satisfied with its performance, you can use it to classify new images. For this, you simply preprocess your images according to the network requirements (i.e., the same way as you did for your dataset used for training the classifier) and apply the classifier using

- `apply_dl_classifier`.

Data for Classification

We distinguish between data used for training and data for inference. Latter one consists of bare images. But for the former one you already know to which class the images belong and provide this information over the corresponding labels.

The training data is used to train a classifier for your specific task. With the aid of this data the classifier can learn which classes are to be distinguished and how their representatives look like. In classification, the image is classified as a whole. Therefore, the training data consists of images and their ground truth labels, thus the class you say this image belongs to. Note that the images should be as representative as possible for your task. There are different possible ways, how to store and retrieve the ground truth labels. The procedure `read_dl_classifier_data_set` supports the following sources of the ground truth label for an image:

- The last directory name containing the image
- The file name.

For training a classifier, we use a technique called transfer learning (see the chapter [Deep Learning](#)). For this, you need less resources, but still a suitable set of data which is generally in the order of hundreds to thousands per class. While in general the network should be more reliable when trained on a larger dataset, the amount of data needed for training also depends on the complexity of the task. You also want enough training data to split it into three subsets, which are preferably independent and identically distributed, see the section “Data” in the chapter [Deep Learning](#).

Regardless of the application, the network poses requirements on the images regarding the image dimensions, the gray value range, and the type. The specific values depend on the network itself and can be queried with `get_dl_classifier_param`. You can find guidance on how to implement such a preprocessing stage by the procedure `preprocess_dl_classifier_images`.

```
apply_dl_classifier (
    Images : : DLClassifierHandle : DLClassifierResultHandle )
```

Infer the class affiliations for a set of images using a deep-learning-based classifier.

`apply_dl_classifier` is obsolete and is only provided for reasons of backward compatibility. New applications should use the general CNN-based operator `apply_dl_model` instead.

`apply_dl_classifier` applies the deep-learning-based classifier given by `DLClassifierHandle` on the set of input images stored in the input object tuple `Images`. It returns the results in the result handle `DLClassifierResultHandle`. For information how to retrieve the corresponding results stored in `DLClassifierResultHandle`, please refer to the documentation of the operator `get_dl_classifier_result`.

The tuple `Images` can contain an arbitrary number of images to be processed in one operator call and is generally independent of the classifier parameter `'batch_size'`. Please notice that this only holds for `apply_dl_classifier` and not for `train_dl_classifier_batch`. This is because `apply_dl_classifier` always classifies a batch with up to `'batch_size'` images simultaneously, whether filled up or not. So in case the number of images in the set `Images` is larger than `'batch_size'`, `apply_dl_classifier` iterates over the necessary number of batches internally. For a `Images` tuple with less than `'batch_size'` images, it is padded to a full batch which means that the runtime of processing for a given batch is independent of whether it is filled up or just consists of a single image. Additionally, if fewer images than `'batch_size'` are classified in one operator call, the network still requires the same amount of memory as for a full batch. Therefore, it is recommended to adapt the `'batch_size'` according to the number of images to be processed in one operator call for greater efficiency. The current value of `'batch_size'` can be retrieved using `get_dl_classifier_param`.

Note that the images must be processed before feeding them into the operator `apply_dl_classifier` in order to have the correct size, gray value range, number of channels and type. We would like to stress the image type: the images must be of type 'real'. For a possibly necessary conversion the operator `convert_image_type` is available. The procedure `preprocess_dl_classifier_images` provides great guidance on how to implement such a preprocessing stage.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Attention

To run this operator, cuDNN and cuBLAS are required when `'runtime'` is set to `'gpu'`, see `set_dl_classifier_param`. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

Parameters

- ▷ **Images** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : real
Tuple of input images.
- ▷ **DLClassifierHandle** (input_control) dl_classifier $\leadsto$ *handle*
Handle of the deep-learning-based classifier.
- ▷ **DLClassifierResultHandle** (output_control) dl_classifier_result $\leadsto$ *handle*
Handle of the deep learning classification results.

Result

If the parameters are valid, the operator `apply_dl_classifier` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`read_dl_classifier`, `train_dl_classifier_batch`, `set_dl_classifier_param`

Possible Successors

`get_dl_classifier_result`, `clear_dl_classifier`

Alternatives

`apply_dl_model`, `classify_class_mlp`, `classify_class_svm`

Module

Deep Learning Inference

```
clear_dl_classifier ( : : DLClassifierHandle : )
```

Clear a deep-learning-based classifier.

clear_dl_classifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the common used CNN-based operator **clear_dl_model** instead.

`clear_dl_classifier` clears the handle of the deep-learning-based classifier given by `DLClassifierHandle`, that was created with `read_dl_classifier`, and frees all memory required for the classifier. After calling `clear_dl_classifier`, the classifier can no longer be used. The handle `DLClassifierHandle` becomes invalid.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Parameters

- ▷ **DLClassifierHandle** (input_control) `dl_classifier(-array) ~ handle`
 Handle of the deep-learning-based classifier.

Result

If the parameters are valid, the operator `clear_dl_classifier` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `DLClassifierHandle`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`read_dl_classifier`, `apply_dl_classifier`, `train_dl_classifier_batch`

Module

Deep Learning Inference

```
clear_dl_classifier_result ( : : DLClassifierResultHandle : )
```

Clear a handle containing the results of the deep-learning-based classification.

clear_dl_classifier_result is obsolete and is only provided for reasons of backward compatibility.

`clear_dl_classifier_result` releases the memory used to store the deep-learning-based classification results given in `DLClassifierResultHandle`. After calling `clear_dl_classifier_result`, the results can no longer be queried. The handle `DLClassifierResultHandle` becomes invalid.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Parameters

- ▷ **DLClassifierResultHandle** (input_control) dl_classifier_result(-array) ~> *handle*
 Handle of the deep learning classification results.

Result

If the parameters are valid, the operator `clear_dl_classifier_result` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`get_dl_classifier_result`, `apply_dl_classifier`

Module

Deep Learning Inference

```
clear_dl_classifier_train_result (
    : : DLClassifierTrainResultHandle : )
```

Clear the handle of a deep-learning-based classifier training result.

clear_dl_classifier_train_result is obsolete and is only provided for reasons of backward compatibility.

`clear_dl_classifier_train_result` clears an arbitrary number of training result handles `DLClassifierTrainResultHandle` of a deep-learning-based classifier. Each of these training result handles has previously been generated using `train_dl_classifier_batch`. All memory allocated in the handles is freed.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Parameters

- ▷ **DLClassifierTrainResultHandle** (input_control) dl_classifier_train_result(-array) ~> *handle*
 Handle of the training results from the deep-learning-based classifier.

Result

If the parameters are valid, the operator `clear_dl_classifier_train_result` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`train_dl_classifier_batch`, `get_dl_classifier_train_result`

Module

Deep Learning Training

```
deserialize_dl_classifier (
    : : SerializedItemHandle : DLClassifierHandle )
```

Deserialize a deep-learning-based classifier.

deserialize_dl_classifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator **deserialize_dl_model**.

`deserialize_dl_classifier` deserializes a deep-learning-based classifier, that was serialized by `serialize_dl_classifier`.

The operator acts the same as `read_dl_classifier` except that the input is a serialized item instead of a file. For a detailed description please refer to the documentation of `read_dl_classifier`.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Parameters

- ▷ **SerializedItemHandle** (input_control) serialized_item $\leadsto$ handle
Handle of the serialized item.
- ▷ **DLClassifierHandle** (output_control) dl_classifier $\leadsto$ handle
Handle of the deep-learning-based classifier.

Result

If the parameters are valid, the operator `deserialize_dl_classifier` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`fread_serialized_item`, `receive_serialized_item`, `serialize_dl_classifier`

Possible Successors

`apply_dl_classifier`, `train_dl_classifier_batch`, `set_dl_classifier_param`,
`get_dl_classifier_param`

Alternatives

`serialize_dl_classifier`

Module

Deep Learning Inference

```
get_dl_classifier_param ( : : DLClassifierHandle,  
    GenParamName : GenParamValue )
```

Return the parameters of a deep-learning-based classifier.

get_dl_classifier_param is obsolete and is only provided for reasons of backward compatibility. New applications should use common CNN-based operator **get_dl_model_param** instead.

`get_dl_classifier_param` returns the parameter values `GenParamValue` of `GenParamName` of the neural network `DLClassifierHandle`.

The hyperparameters and network parameters can be set with the operator `set_dl_classifier_param`, in whose reference entry they are described in detail. With `get_dl_classifier_param` you can query all these values.

Additionally, there are parameters defined by the network which are read-only. These parameters are:

'image_range_min': Minimum gray value.

'image_range_max': Maximum gray value.

The precise values for these parameters and the default parameters for the image dimension depend on the concrete network, see [read_dl_classifier](#).

Every image that is fed into the network must be present according to the parameters defining the image properties. To preprocess images accordingly, the procedure `preprocess_dl_classifier_images` is available.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Parameters

- ▷ **DLClassifierHandle** (input_control) `dl_classifier` $\leadsto$ *handle*
Handle of the deep-learning-based classifier.
- ▷ **GenParamName** (input_control) `attribute.name(-array)` $\leadsto$ *string*
Name of the generic parameter.
Default: 'gpu'
List of values: `GenParamName` $\in$ {'batch_size', 'batch_size_multiplier', 'classes', 'gpu', 'image_dimensions', 'image_num_channels', 'image_height', 'image_range_max', 'image_range_min', 'image_width', 'learning_rate', 'momentum', 'runtime', 'runtime_init', 'weight_prior'}
- ▷ **GenParamValue** (output_control) `attribute.name(-array)` $\leadsto$ *integer / string / real*
Value of the generic parameter.

Result

If the parameters are valid, the operator `get_dl_classifier_param` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[read_dl_classifier](#), [set_dl_classifier_param](#)

Possible Successors

[train_dl_classifier_batch](#), [apply_dl_classifier](#)

Alternatives

[get_dl_model_param](#)

See also

[set_dl_classifier_param](#)

Module

Deep Learning Inference

```
get_dl_classifier_result ( : : DLClassifierResultHandle, Index,
    GenResultName : GenResultValue )
```

Retrieve classification results inferred by a deep-learning-based classifier.

`get_dl_classifier_result` is obsolete and is only provided for reasons of backward compatibility.

`get_dl_classifier_result` allows the user to return classification results. These results are stored in the handle [DLClassifierResultHandle](#) and have been obtained from the operator [apply_dl_classifier](#).

The input parameter [GenResultName](#) names the sort of result asked and [Index](#) identifies for which image the result is to be returned. The respective value is given in [GenResultValue](#).

Concretely, [GenResultName](#) can attain the following values:

'*confidences*': return the confidences values for the selected image [Index](#).

'*predicted_classes*': return the names of the inferred classes for the selected image [Index](#).

'*predicted_class_indices*': return the indices of the inferred classes for the selected image [Index](#). The class indices correspond to the positions within the array of classes (counting from 0).

The input parameter [Index](#) can attain the value 'all', in which case `get_dl_classifier_result` returns the confidence value, respectively class, for the best candidate (prediction with the highest confidence value) for each image of the input batch.

Otherwise, [Index](#) must be an integer selecting one of the input images in the batch, in which case `get_dl_classifier_result` returns all output classes, respectively, confidences sorted by decreasing confidence value. This is useful in order to retrieve the best K candidates for a given input. As we start indexing at 0, [Index](#) must have a value between 0 and the size of the batch of input images minus one.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Parameters

- ▷ **DLClassifierResultHandle** (input_control) `dl_classifier_result` $\leadsto$ *handle*
Handle of the deep learning classification results.
- ▷ **Index** (input_control) `number` $\leadsto$ *string / integer*
Index of the image in the batch.
Default: 'all'
- ▷ **GenResultName** (input_control) `attribute.name(-array)` $\leadsto$ *string*
Name of the generic parameter.
Default: 'predicted_classes'
List of values: `GenResultName` $\in$ {'predicted_classes', 'predicted_class_indices', 'confidences'}
- ▷ **GenResultValue** (output_control) `attribute.value(-array)` $\leadsto$ *real / string / integer*
Value of the generic parameter, either the confidence values, the class names or class indices.

Result

If the parameters are valid, the operator `get_dl_classifier_result` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[apply_dl_classifier](#)

Possible Successors

[clear_dl_classifier_result](#)

Module

Deep Learning Inference

```
get_dl_classifier_train_result (
    : : DLClassifierTrainResultHandle, GenParamName : GenParamValue )
```

Return the results for the single training step of a deep-learning-based classifier.

`get_dl_classifier_train_result` is obsolete and is only provided for reasons of backward compatibility.

`get_dl_classifier_train_result` returns the value [GenParamValue](#) of the result [GenParamName](#) of a deep learning training handle [DLClassifierTrainResultHandle](#).

The options for [GenParamValue](#) are the following:

'loss' or 'total_loss': Current value of the loss function. See [train_dl_classifier_batch](#) for a detailed explanation of the loss function.

'mll_loss': Current value of the loss function, i.e. 'loss', without 'regularization_loss'.

'regularization_loss': Current value of the regularization loss function, i.e. 'loss' without 'mll_loss'.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Parameters

- ▷ **DLClassifierTrainResultHandle** (input_control) dl_classifier_train_result $\leadsto$ handle
Handle of the training results from the deep-learning-based classifier.
- ▷ **GenParamName** (input_control) attribute.name(-array) $\leadsto$ string
Name of the generic parameter.
Default: 'loss'
List of values: GenParamName $\in$ {'loss', 'mll_loss', 'regularization_loss', 'total_loss'}
- ▷ **GenParamValue** (output_control) attribute.name(-array) $\leadsto$ real / integer / string
Value of the generic parameter.

Result

If the parameters are valid, the operator `get_dl_classifier_train_result` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

[clear_dl_classifier_train_result](#)

Module

Deep Learning Training

read_dl_classifier (: : FileName : DLClassifierHandle)

Read a deep-learning-based classifier from a file.

read_dl_classifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator [read_dl_model](#).

The operator `read_dl_classifier` reads a neural network written by [write_dl_classifier](#). As a result, the handle `DLClassifierHandle` is returned.

HALCON provides pretrained neural networks. These neural networks are good starting points to train a custom classifier for image classification. They have been pretrained on a large image dataset. The provided pretrained neural networks are:

'pretrained_dl_classifier_compact.hdl': This neural network is designed to be memory and runtime efficient.

This classifier expects the images to be of the type `real`. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with [get_dl_classifier_param](#). Here we list the default values with which the classifier has been trained:

'image_width': 224

'image_height': 224

'image_num_channels': 3

```
'image_range_min': -127.0
'image_range_max': 128.0
```

This network does not contain any fully connected layer. The network architecture allows changes concerning the image dimensions, but requires a minimum *'image_width'* and *'image_height'* of 15 pixels.

'pretrained_dl_classifier_enhanced.hdl': This neural network has more hidden layers than *'pretrained_dl_classifier_compact.hdl'* and is therefore assumed to be better suited for more complex classification tasks. But this comes at the cost of being more time and memory demanding. As a result, e.g., in comparison to the above compact network, the batch size has to be decreased network during the training, see [set_dl_classifier_param](#).

This classifier expects the images to be of the type `real`. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with [get_dl_classifier_param](#). Here we list the default values with which the classifier has been trained:

```
'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127.0
'image_range_max': 128.0
```

The network architecture allows changes concerning the image dimensions, but requires a minimum *'image_width'* and *'image_height'* of 47 pixels. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Changing the image size will reinitialize the weights of the fully connected layers and therefore makes a retraining necessary.

'pretrained_dl_classifier_resnet18.hdl': As the neural network *'pretrained_dl_classifier_enhanced.hdl'*, this classifier is suited for more complex tasks. But its structure differs, bringing the advantage of making the training more stable and being internally more robust. Compared to the neural network *'pretrained_dl_classifier_resnet50.hdl'* it is less complex and has faster inference times.

This classifier expects the images to be of the type `real`. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with [get_dl_classifier_param](#). Here we list the default values with which the classifier has been trained:

```
'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127.0
'image_range_max': 128.0
```

The network architecture allows changes concerning the image dimensions, but a minimum *'image_width'* and *'image_height'* of 32 pixels is recommended. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Despite the fully connected layer a change of the image size does not lead to a reinitialization of the weights.

'pretrained_dl_classifier_resnet50.hdl': As the neural network *'pretrained_dl_classifier_enhanced.hdl'*, this classifier is suited for more complex tasks. But its structure differs, bringing the advantage of making the training more stable and being internally more robust.

This classifier expects the images to be of the type `real`. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with [get_dl_classifier_param](#). Here we list the default values with which the classifier has been trained:

```
'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127.0
'image_range_max': 128.0
```

The network architecture allows changes concerning the image dimensions, but a minimum *'image_width'* and *'image_height'* of 32 pixels is recommended. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Despite the fully connected layer a change of the image size does not lead to a reinitialization of the weights.

The values listed above are the default image dimensions and gray value range for the networks and these are the values with which the classifiers have been trained. The network architectures allow different image sizes which can be set with `set_dl_classifier_param`. For networks with at least one fully connected layer such a change makes a retraining necessary. Networks without fully connected layers are directly applicable to different image sizes. However, images with a size differing from the size with which the classifier has been trained are likely to show a reduced classification accuracy.

The actually configured dimensions can be queried by `get_dl_classifier_param`. Every image that is fed into a network must be present according to the required dimensions. To adjust images accordingly, the procedure `preprocess_dl_classifier_images` is available.

Typically it is easier, faster and better to retrain a pretrained classifier for a given classification problem. A pretrained classifier has already learned good general purpose features. To retrain the network for a custom problem, the new 'classes' of the classifier have to be set with `set_dl_classifier_param`.

The neural network is loaded from the file `FileName`. This file is hereby searched in the directory (\$HALCON-ROOT/dl/) as well as in the currently used directory.

Please note that the runtime specific parameter 'gpu' of the classifier is not read from file. Instead it is initialized with its default value (see `set_dl_classifier_param`).

The default HALCON file extension for deep learning classifiers is '.hdl'.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ string
File name.
Default: 'pretrained_dl_classifier_compact.hdl'
List of values: `FileName` $\in$ {'pretrained_dl_classifier_compact.hdl',
'pretrained_dl_classifier_enhanced.hdl', 'pretrained_dl_classifier_resnet18.hdl',
'pretrained_dl_classifier_resnet50.hdl' }
File extension: .hdl
- ▷ **DLClassifierHandle** (output_control) dl_classifier $\leadsto$ handle
Handle of the deep learning classifier.

Result

If the indicated file is available and the format is correct, the operator `read_dl_classifier` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`set_dl_classifier_param`, `get_dl_classifier_param`, `apply_dl_classifier`,
`train_dl_classifier_batch`

Alternatives

`read_dl_model`, `read_class_mlp`, `read_class_svm`

Module

Deep Learning Inference

```
serialize_dl_classifier (
    : : DLClassifierHandle : SerializedItemHandle )
```

Serialize a deep-learning-based classifier.

serialize_dl_classifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator **serialize_dl_model**.

`serialize_dl_classifier` serializes a deep-learning-based classifier (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The classifier is defined by the handle `DLClassifierHandle`. The serialized classifier is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_dl_classifier`.

The operator acts the same as `write_dl_classifier` except that the output is a serialized item instead of a file. For a detailed description please refer to the documentation of `write_dl_classifier`.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Parameters

- ▷ **DLClassifierHandle** (input_control) dl_classifier $\leadsto$ handle
Handle of the deep-learning-based classifier.
- ▷ **SerializedItemHandle** (output_control) serialized_item $\leadsto$ handle
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_dl_classifier` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`train_dl_classifier_batch`

Possible Successors

`apply_dl_classifier`, `train_dl_classifier_batch`, `fwrite_serialized_item`,
`send_serialized_item`, `set_dl_classifier_param`, `get_dl_classifier_param`

Deep Learning Inference

```
set_dl_classifier_param ( : : DLClassifierHandle,  GenParamName,
                          GenParamValue : )
```

Set the parameters of a deep-learning-based classifier.

set_dl_classifier_param is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator **set_dl_model_param** instead.

`set_dl_classifier_param` sets the parameters and hyperparameters `GenParamName` of the neural network `DLClassifierHandle` to the values `GenParamValue`.

The pretrained classifiers are trained for their default image dimensions, see `read_dl_classifier`.

The network architectures allow different image dimensions. But for networks with at least one fully connected layer such a change makes a retraining necessary. Networks without fully connected layers are directly applicable to different image sizes. However, images with a size differing from the size with which the classifier has been trained, are likely to show a reduced classification accuracy.

`GenParamName` can attain the following values:

'batch_size': Number of images (and corresponding labels) in a batch that is transferred to device memory. The batch of images which are processed simultaneously in a single training iteration contains a number of images which is equal to **'batch_size'** times **'batch_size_multiplier'**. Please refer to [train_dl_classifier_batch](#) for further details. The parameter **'batch_size'** is stored in the pretrained classifier. Per default, the **'batch_size'** is set such that a training of the pretrained classifier with up to 100 classes can be easily performed on a device with 8 gigabyte of memory. For the pretrained classifiers, the default values are hence given as follows:

pretrained classifier	default value of 'batch_size'
'pretrained_dl_classifier_compact.hdl'	160
'pretrained_dl_classifier_enhanced.hdl'	96
'pretrained_dl_classifier_resnet18.hdl'	24
'pretrained_dl_classifier_resnet50.hdl'	23

For inference, the **'batch_size'** can be generally set independently from the number of input images. See [apply_dl_classifier](#) for details on how to set this parameter for greater efficiency.

'batch_size_multiplier': Multiplier for **'batch_size'** to enable training with larger numbers of images in one step which would otherwise not be possible due to GPU memory limitations. For detailed information see [train_dl_classifier_batch](#). This model parameter does not have any impact during evaluation and inference. For the pretrained classifiers, the default value of **'batch_size_multiplier'** is set to 1.

'classes': Tuple of labels corresponding to the classes of objects which are to be recognized. The order of the class names remains unchanged after the setting.

'gpu': Identifier of the GPU where the training and inference operators ([train_dl_classifier_batch](#) and [apply_dl_classifier](#)) are executed. Per default, the first available GPU is used. [get_system](#) with **'cuda_devices'** can be used to retrieve a list of available GPUs. Pass the index in this list to **'gpu'**.

'image_width': Width of the images the network will process. The default value is given by the network, see [read_dl_classifier](#).

'image_height': Height of the images the network will process. The default value is given by the network, see [read_dl_classifier](#).

'image_num_channels': Number of channels of the images the network will process. Possible are one channel (gray value image), or three channels (three-channel image). The default value is given by the network, see [read_dl_classifier](#). Changing to a single channel image modifies the network configuration. This process removes the color information contained in certain layers and is not invertible.

'image_dimensions': Tuple containing the image dimensions **'image_width'**, **'image_height'**, and number of channels **'image_num_channels'**. The default values are given by the network, see [read_dl_classifier](#). Concerning the number of channels, the values one (gray value image), or three (three-channel image) are possible. Changing to a single channel image modifies the network configuration. This process removes the color information contained in certain layers and is not invertible.

'learning_rate': Initial value of the factor determining the gradient influence during training. Please refer to [train_dl_classifier_batch](#) for further details. The default value depends on the classifier.

'momentum': When updating the arguments of the loss function, the hyperparameter **'momentum'** specifies to which extent previous updating vectors will be added to the current updating vector. Please refer to [train_dl_classifier_batch](#) for further details. Per default, the **'momentum'** is set to 0.9.

'runtime': Defines the device on which the operators will be executed. Per default, the **'runtime'** is set to **'gpu'**.

'cpu': The operator [apply_dl_classifier](#) will be executed on the CPU, whereas the operator [train_dl_classifier_batch](#) is not executable.

In case the GPU has been used before, CPU memory is initialized, and if necessary values stored on the GPU memory are moved to the CPU memory.

On Intel or AMD architectures the **'cpu'** runtime uses OpenMP for the parallelization of [apply_dl_classifier](#), where per default, all threads available to the OpenMP runtime are used. You may use the [set_system](#) parameter **'thread_num'** to specify the number of threads.

On Arm architectures the **'cpu'** runtime uses a global thread pool. You may specify the number of threads with the [set_system](#) parameter **'thread_num'**.

For both architectures mentioned above, it is not possible to specify a thread-specific number of threads (via the parameter **'tsp_thread_num'** of the operator [set_system](#)).

'gpu': The GPU memory is initialized and the corresponding handle created. The operators `apply_dl_classifier` and `train_dl_classifier_batch` will be executed on the GPU. For the specific requirements please refer to the HALCON "Installation Guide".

'runtime_init': If called with *'immediately'*, the GPU memory is initialized and the corresponding handle created. Otherwise this is done on demand, which may result in significantly larger execution times for the first call of `apply_dl_classifier` or `train_dl_classifier_batch`. If *'gpu'* or *'batch_size'* is changed with subsequent calls of `set_dl_classifier_param`, the GPU memory is reinitialized.

Note, this parameter has no effect if running on CPUs, thus if *'runtime'* is set to *'cpu'*.

'weight_prior': Regularization parameter $\alpha \geq 0.0$ used for l_2 regularization of the loss function. Regularization is helpful in the presence of overfitting during the classifier training. If the hyperparameter *'weight_prior'* is non-zero, the regularization term given below is added to the loss function (see also `train_dl_classifier_batch`)

$$E_{\alpha}(w) = \frac{\alpha}{2} \sum_{k=0}^{K-1} |w_k|^2$$

Here the index k runs over all weights of the network, except for the biases which are not regularized. The regularization term $E_{\alpha}(w)$ generally penalizes large weights, thus pushing the weights towards zero, which effectively reduces the complexity of the model. Simply put: Regularization favors simpler models that are less likely to learn noise in the data and generalize better. In case the classifier overfits the data, it is strongly recommended to try different values for the parameter *'weight_prior'* to improve the generalization properties of the neural network. Choosing its value is a trade-off between the models ability to generalize, overfitting, and underfitting. If α is too small, the model might overfit, if its too large the model might loose its ability to fit the data, because all weights are effectively zero. For finding an ideal value for α , we recommend a cross-validation, i.e. to perform the training for a range of values and choose the value that results in the best validation error. For typical applications, we recommend testing the values for *'weight_prior'* on a logarithmic scale between 1.0, ..., 0.0001. If the training takes a very long time, one might consider performing the hyperparameter optimization on a reduced amount of data. The default value depends on the classifier.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Attention

To successfully set *'gpu'* parameters, cuDNN and cuBLAS are required, i.e., to set the parameter `GenParamName` *'runtime'* to *'gpu'* or to set the `GenParamName` *'gpu'*. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

Parameters

- ▷ **DLClassifierHandle** (input_control) dl_classifier $\leadsto$ handle
Handle of the deep-learning-based classifier.
- ▷ **GenParamName** (input_control) attribute.name(-array) $\leadsto$ string
Name of the generic parameter.
Default: 'classes'
List of values: `GenParamName` $\in$ {'batch_size', 'batch_size_multiplier', 'classes', 'gpu', 'image_dimensions', 'image_num_channels', 'image_height', 'image_width', 'learning_rate', 'momentum', 'runtime', 'runtime_init', 'weight_prior' }
- ▷ **GenParamValue** (input_control) attribute.value(-array) $\leadsto$ string / real / integer
Value of the generic parameter.
Default: ['class_1', 'class_2', 'class_3']
Suggested values: `GenParamValue` $\in$ {1, 2, 3, 50, 0.001, 'cpu', 'gpu', 'immediately' }

Result

If the parameters are valid, the operator `set_dl_classifier_param` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Deep Learning Inference	

```
train_dl_classifier_batch ( BatchImages : : DLClassifierHandle,
    BatchLabels : DLClassifierTrainResultHandle )
```

Perform a training step of a deep-learning-based classifier on a batch of images.

train_dl_classifier_batch is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator [train_dl_model_batch](#).

[train_dl_classifier_batch](#) performs a training step of the deep-learning-based classifier contained in [DLClassifierHandle](#). The classifier handle [DLClassifierHandle](#) has to be read previously using [read_dl_classifier](#). In order to apply training steps, classes have to be specified using [set_dl_classifier_param](#). Other hyperparameters such as the learning rate and the momentum are also important for a successful training. They are set using [set_dl_classifier_param](#).

The training step is done on basis of a single batch of images from the training dataset, thus the images [BatchImages](#) with labels [BatchLabels](#). The number of images within the batch needs to be a multiple of the 'batch_size' where the parameter 'batch_size' is limited by the amount of available GPU memory. In order to process more images in one training step, the classifier parameter 'batch_size_multiplier' can be set to a value greater than 1. The number of images being passed to the training operator needs to be equal to 'batch_size' times 'batch_size_multiplier'. Note that a training step calculated for a batch and a 'batch_size_multiplier' greater 1 is an approximation of a training step calculated for the same batch but with a 'batch_size_multiplier' equal to 1 and an accordingly greater 'batch_size'. As an example, the loss calculated with a 'batch_size' of 4 and a 'batch_size_multiplier' of 2 is usually not equal to the loss calculated with a 'batch_size' of 8 and a 'batch_size_multiplier' of 1, although the same number of images is used for training in both cases. However, the approximation generally delivers comparably good results, so it can be utilized if you wish to train with a larger number of images than your GPU allows. In some rare cases the approximation with a 'batch_size' of 1 and an accordingly large 'batch_size_multiplier' does not show the expected performance which for example can happen when the pretrained network 'pretrained_dl_classifier_resnet50.hdl' is used. Setting the 'batch_size' to a value greater than 1 can help to solve this issue.

Note that the images in [BatchImages](#) must fulfill certain conditions regarding, for example, the image size and gray value range, depending on the chosen network. Please have a look at [read_dl_classifier](#) and [set_dl_classifier_param](#) for more information. The labels in [BatchLabels](#) can be handed over as an array of strings, or as an array of indices corresponding to the position of the label within the array of classes (counting from 0) set before via 'classes' with [set_dl_classifier_param](#). Information about the results of the training step as the value of the loss are stored in [DLClassifierTrainResultHandle](#) and can be accessed using [get_dl_classifier_train_result](#).

Note that an epoch generally consists of a large number of batches and that a successful training involves many epochs. Therefore [train_dl_classifier_batch](#) has to be applied several times with different batches. For a more detailed explanation, we refer to [Legacy / DL Classification](#).

During training, a nonlinear optimization algorithm minimizes the value of the loss function. The later one is determined based on the prediction of the neural network on the current batch of images. The algorithm used for optimization is stochastic gradient descent (SGD). It updates the layers' weights of the previous iteration w_t to the new values w_{t+1} at iteration $t + 1$ as follows:

$$\begin{aligned} v^{t+1} &= \mu v^t - \lambda \nabla_w L(f(x, w^t)) \\ w^{t+1} &= w^t + v^{t+1}. \end{aligned}$$

Here, λ is the learning rate, μ for the momentum, and $f(x, w)$ for the classification result of the deep learning-based classifier which depends on the network weights w and the input batch x . The variable v_t is used to involve the influence of the momentum μ . The loss function used here is the Multinomial Logistic Loss in combination with a quadratic regularization term $E_\alpha(w)$,

$$L(f(x, w)) = -\frac{1}{N} \sum_{n=0}^{N-1} \langle y_n, \log(f(x_n, w)) \rangle + E_\alpha(w), \quad E_\alpha(w) = \frac{\alpha}{2} \sum_{k=0}^{K-1} |w_k|^2.$$

Here, y_n is a one-hot encoded target vector that encodes the label of the n -th image x_n of the batch x containing N -many images, and $\log(f(x_n, w))$ shall be understood to be a vector such that $\log$ is applied on each component of $f(x_n, w)$. The regularization term $E_\alpha(w)$ is a weighted l^2 -norm involving all K weights except for biases. Its influence can be controlled through α . In the above formula, α denotes the hyperparameter 'weight_prior' that can be set with `set_dl_classifier_param`. In order to gain more insight, you can retrieve the current value of the total loss function as well as individual contributions using `get_dl_classifier_train_result`.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Attention

The operator `train_dl_classifier_batch` internally calls functions that might not be deterministic. Therefore, results from multiple calls of `train_dl_classifier_batch` can slightly differ, although the same input values have been used.

To run this operator, cuDNN and cuBLAS are required. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

Parameters

- ▷ **BatchImages** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : real
Images comprising the batch.
- ▷ **DLClassifierHandle** (input_control) dl_classifier $\leadsto$ *handle*
Handle of the deep-learning-based classifier.
- ▷ **BatchLabels** (input_control) string-array $\leadsto$ *string* / integer
Corresponding labels for each of the images.
Default: []
List of values: BatchLabels $\in$ {[]}
- ▷ **DLClassifierTrainResultHandle** (output_control) dl_classifier_train_result $\leadsto$ *handle*
Handle of the training results from the deep-learning-based classifier.

Result

If the parameters are valid, the operator `train_dl_classifier_batch` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

write_dl_classifier (: : DLClassifierHandle, FileName :)

Write a deep-learning-based classifier in a file.

write_dl_classifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the common CNN-based operator [write_dl_model](#) instead.

[write_dl_classifier](#) writes the deep-learning-based classifier [DLClassifierHandle](#) to the file given by [FileName](#).

[write_dl_classifier](#) is typically called after the classifier has been trained with [train_dl_classifier_batch](#). The classifier can be read with [read_dl_classifier](#).

Please note that the runtime specific parameter 'gpu' of the classifier is not written.

The default HALCON file extension for deep learning classifiers is '.hdl'.

For an explanation of the concept of deep-learning-based classification see the introduction of chapter [Deep Learning / Classification](#). The workflow involving this legacy operator is described in the chapter [Legacy / DL Classification](#).

Parameters

- ▷ **DLClassifierHandle** (input_control) dl_classifier ~> handle
Handle of the deep-learning-based classifier.
- ▷ **FileName** (input_control) filename.write ~> string
File name.
File extension: .hdl

Result

If the parameters are valid, the operator [write_dl_classifier](#) returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

17.5 Develop

dev_map_par (: : :)

Open the dialog to specify the visualization parameters.

dev_map_par is obsolete and is only provided for reasons of backward compatibility. New applications should use **dev_open_tool** with **ToolName** set to *'visualization_parameters_dialog'* instead.

dev_map_par opens the Visualization Parameter dialog. This can also be achieved interactively via the menu Visualization▷Set Parameters... or the appropriate tool bar button. The dialog is used to configure the visualization parameters that are used to display iconic objects.

Attention

This operator is not supported for code export.

Example

```
read_image (Image, 'fabrik')
threshold (Image, Region, 128, 255)
dev_map_par ()
```

Result

dev_map_par returns always 2 (H_MSG_TRUE).

Possible Successors

[dev_unmap_par](#)

Module

Foundation

dev_map_prog (: : :)

Make the main window of HDevelop visible.

dev_map_prog is obsolete and is only provided for reasons of backward compatibility. New applications should use **dev_open_tool** with **ToolName** set to *'program_window'* instead.

dev_map_prog is used to re-show (map) the main window of HDevelop after it has been hidden (unmapped) by [dev_unmap_prog](#).

Attention

This operator is not supported for code export.

Depending on the operating system or the window manager the execution of **dev_map_prog** will result only in a visible icon of the window. In this case it has to be opened by the user with mouse interaction.

Result

dev_map_prog always returns 2 (H_MSG_TRUE).

dev_unmap_par (: : :)

Closes the dialog to specify the visualization parameters.

dev_unmap_par is obsolete and is only provided for reasons of backward compatibility. New applications should use **dev_close_tool** with ToolId set to 'visualization_parameters_dialog' instead.

dev_unmap_par closes the Visualization Parameter dialog. This can also be achieved interactively by pressing the Close button on the dialog's title bar. The dialog can be opened again by [dev_map_par](#).

Attention

This operator is not supported for code export.

Result

dev_unmap_par always returns 2 (H_MSG_TRUE).

Possible Successors

[dev_map_par](#)

[dev_map_par](#), [dev_map_prog](#), [dev_map_var](#)

Module

Foundation

dev_unmap_prog (: : :)

Hide the main window.

dev_unmap_prog is obsolete and is only provided for reasons of backward compatibility. New applications should use **dev_close_tool** with ToolId set to 'program_window' instead.

dev_unmap_prog hides in MDI mode the main window and in SDI mode the program window so that it is no longer visible. It can be shown again by [dev_map_prog](#).

Attention: after hiding the main window there is no opportunity to enter and execute the [dev_map_prog](#) operator. So take care that dev_unmap_prog is only executed in continuous mode with a reachable [dev_map_prog](#) operator.

Attention

This operator is not supported for code export.

Result

dev_unmap_prog always returns 2 (H_MSG_TRUE).

Possible Successors

[dev_map_prog](#), [stop](#)

17.6 Filters

```
gauss_image ( Image : ImageGauss : Size : )
```

Smooth an image using discrete Gaussian functions.

gauss_image is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator **gauss_filter** instead.

The operator **gauss_image** smoothes images using the discrete Gaussian. The smoothing effect increases with increasing filter size. The following filter sizes (**Size**) are supported (the sigma value of the Gauss function is indicated in brackets):

3	(0.65)
5	(0.87)
7	(1.43)
9	(1.88)
11	(2.31)

For border treatment the gray values of the images are reflected at the image borders.

The operator **binomial_filter** can be used as an alternative to **gauss_image**. **binomial_filter** is significantly faster than **gauss_image**. It should be noted that the mask size in **binomial_filter** does not lead to the same amount of smoothing as the mask size in **gauss_image**. Corresponding mask sizes can be determined based on the respective values of the Gaussian smoothing parameter sigma.

gauss_image can be executed on OpenCL devices for all supported image types. However, the OpenCL implementation can produce slightly different results from the scalar implementation.

For an explanation of the concept of smoothing filters see the introduction of chapter [Filters / Smoothing](#).

Attention

In order to be able to process **gauss_image** on an OpenCL device, **Image** must be at least 64 pixels in both width and height.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter [Filters](#).

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ object : byte / int2 / uint2 / int4 / real
Image to be smoothed.
- ▷ **ImageGauss** (output_object) (multichannel-)image(-array) $\leadsto$ object : byte / int2 / uint2 / int4 / real
Filtered image.
- ▷ **Size** (input_control) integer $\leadsto$ integer
Required filter size.
Default: 5
List of values: Size $\in \{3, 5, 7, 9, 11\}$

Example

```
gauss_image (Input, Gauss, 7)
regiongrowing (Gauss, Segments, 7, 7, 5, 100)
```

Complexity

For each pixel: $O(Size * 2)$.

Result

If the parameter values are correct the operator `gauss_image` returns the value 2 (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system('no_object_result', <Result>)`. If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module

Foundation

```
polar_trans_image ( ImageXY : ImagePolar : Row, Column, Width,
                    Height : )
```

Transform an image to polar coordinates

polar_trans_image is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator [polar_trans_image_ext](#) instead.

`polar_trans_image` transforms an image in Cartesian coordinates to an image in polar coordinates. The size of the resulting image is selected with `Width` and `Height`. `Width` determines the angular resolution, while `Height` determines the resolution of the radius. `Row` and `Column` determine the center of the polar coordinate system in the original image `ImageXY`. This point is mapped to the upper row of `ImagePolar`.

A point (x',y') in the result image corresponds to the point (x,y) in the original image in the following manner:

$$\begin{aligned} x &= y' * \cos(2\pi(x'/result_width)) + Column \\ y &= y' * \sin(2\pi(x'/result_width)) + Row. \end{aligned}$$

`polar_trans_image` can be executed on an OpenCL device if the input image does not exceed the maximum size of image objects of the selected device. Due to numerical reasons, there can be slight differences in the output compared to the execution on the CPU.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter [Transformations / 2D Transformations](#).

Parameters

- ▷ **ImageXY** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / int2 / uint2 / real
Input image in Cartesian coordinates.
- ▷ **ImagePolar** (output_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / int2 / uint2 / real
Result image in polar coordinates.
- ▷ **Row** (input_control) point.y $\leadsto$ *integer*
Row coordinate of the center of the coordinate system.
Default: 100
Suggested values: Row $\in$ {0, 10, 100, 200}
Value range: $0 \leq \text{Row} \leq 512$
Minimum increment: 1
Recommended increment: 1
- ▷ **Column** (input_control) point.x $\leadsto$ *integer*
Column coordinate of the center of the coordinate system.
Default: 100
Suggested values: Column $\in$ {0, 10, 100, 200}
Value range: $0 \leq \text{Column} \leq 512$
Minimum increment: 1
Recommended increment: 1
- ▷ **Width** (input_control) extent.x $\leadsto$ *integer*
Width of the result image.
Default: 314
Suggested values: Width $\in$ {100, 200, 157, 314, 512}
Value range: $2 \leq \text{Width} \leq 512$
Minimum increment: 1
Recommended increment: 10
- ▷ **Height** (input_control) extent.y $\leadsto$ *integer*
Height of the result image.
Default: 200
Suggested values: Height $\in$ {100, 128, 256, 512}
Value range: $2 \leq \text{Height} \leq 512$
Minimum increment: 1
Recommended increment: 10

Example

```
read_image(Image, 'monkey')
dev_display (Image)
polar_trans_image(Image, PolarImage, 100, 100, 314, 200)
dev_display (PolarImage)
```

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Module

Foundation

17.7 Graphics

```
clear_rectangle ( : : WindowHandle, Row1, Column1, Row2,
                  Column2 : )
```

Delete a rectangle on the output window.

clear_rectangle is obsolete and is only provided for reasons of backward compatibility.

`clear_rectangle` deletes all entries in the rectangle which is defined through the upper left corner (`Row1,Column1`) and the lower right corner (`Row2,Column2`). Deletion means that the specified rectangle is set to the background color (see `open_window`).

If you want to delete more than one rectangle, you may pass several rectangles, i.e., the parameters `Row1`, `Column1`, `Row2` and `Column2` are tuples.

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **Row1** (input_control) rectangle.origin.y(-array) $\leadsto$ *integer*
Line index of upper left corner.
Default: 10
Value range: $0 \leq \text{Row1} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Column1** (input_control) rectangle.origin.x(-array) $\leadsto$ *integer*
Column index of upper left corner.
Default: 10
Value range: $0 \leq \text{Column1} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Row2** (input_control) rectangle.corner.y(-array) $\leadsto$ *integer*
Row index of lower right corner.
Default: 118
Value range: $0 \leq \text{Row2} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
Restriction: `Row2 > Row1`
- ▷ **Column2** (input_control) rectangle.corner.x(-array) $\leadsto$ *integer*
Column index of lower right corner.
Default: 118
Value range: $0 \leq \text{Column2} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
Restriction: `Column2 >= Column1`

Example

* Erase a rectangle in the output window interactively:
`draw_rectangle1(WindowHandle,L1,C1,L2,C2)`

Result

If an output window exists and the specified parameters are correct `clear_rectangle` returns 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`, `set_draw`, `set_color`, `set_colored`, `set_line_width`, `set_rgb`, `set_hsi`, `draw_rectangle1`

Alternatives

`clear_window`, `disp_rectangle1`

See also

`open_window`

Module

Foundation

disp_distribution (: : WindowHandle, Distribution, Row, Column, Scale :)

Displays a noise distribution.

disp_distribution is obsolete and is only provided for reasons of backward compatibility.

`disp_distribution` displays a distribution in the window. `Row` and `Column` define the position of the center of the graphic. `Scale` allows scaling of the graphic, whereby 1 means displaying all 256 values, 2 means displaying 128 values, 3 means displaying only 64 values, etc. Noise distributions can be generated with operations like `gauss_distribution` or `noise_distribution_mean`.

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **Distribution** (input_control) real-array $\leadsto$ *real*
Gray value distribution (513 values).
- ▷ **Row** (input_control) point.y $\leadsto$ *integer*
Row index of center.
Default: 256
Suggested values: Row $\in$ {0, 64, 128, 256}
Value range: $0 \leq \text{Row} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 10
- ▷ **Column** (input_control) point.x $\leadsto$ *integer*
Column index of center.
Default: 256
Suggested values: Column $\in$ {0, 64, 128, 256}
Value range: $0 \leq \text{Column} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 10
- ▷ **Scale** (input_control) integer $\leadsto$ *integer*
Size of display.
Default: 1
Suggested values: Scale $\in$ {1, 2, 3, 4, 5, 6}

Example

```
open_window(0,0,-1,-1,'root','visible','',WindowHandle)
set_draw(WindowHandle,'fill')
set_color(WindowHandle,'white')
read_image(Image,'monkey')
draw_region(Region,WindowHandle)
noise_distribution_mean(Region,Image,21,Distribution)
disp_distribution (WindowHandle,Distribution,100,100,3)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

disp_lut (: : WindowHandle, Row, Column, Scale :)
--

Graphical view of the look-up-table (lut).

disp_lut is obsolete and is only provided for reasons of backward compatibility.

`disp_lut` displays a graphical view of the look-up-table (lut) in the valid window. A look-up-table defines the transformation of image gray values to colors/gray levels on the screen. On most systems this can be modified. `disp_lut` creates a graphical view of the table assigned to the output window with the logical window number `WindowHandle` and displays it for every basic color (red, green, blue). `Row` and `Column` define the position of the center of the graphic. `Scale` allows scaling of the graphic, whereby 1 means displaying all 256 values, 2 means displaying 128 values, 3 means displaying only 64 values, etc. Tables for monochrome-representations are displayed in the currently set color (see [set_color](#), [set_rgb](#), etc.). Tables for displaying “false colors” are viewed with red, green and blue for each color component.

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ handle
Window handle.
- ▷ **Row** (input_control) point.y $\leadsto$ integer
Row of center of the graphic.
Default: 128
Value range: $0 \leq \text{Row} \leq 511$
- ▷ **Column** (input_control) point.x $\leadsto$ integer
Column of center of the graphic.
Default: 128
Value range: $0 \leq \text{Column} \leq 511$
- ▷ **Scale** (input_control) integer $\leadsto$ integer
Scaling of the graphic.
Default: 1
List of values: $\text{Scale} \in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$
Value range: $0 \leq \text{Scale} \leq 20$

Result

`disp_lut` returns 2 (H_MSG_TRUE) if the hardware supports a look-up-table, the window is valid and the parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

get_comprise (: : WindowHandle : Mode)

*Get the output treatment of an image matrix.***get_comprise** is obsolete and is only provided for reasons of backward compatibility.

`get_comprise` returns the output mode of gray values in the window `WindowHandle` that is used by `disp_image` and `disp_color`. The output mode defines whether only the gray values of objects are displayed or the whole image is displayed. The query is used for temporary mode settings, i.e., the current mode is queried, then overwritten with (`set_comprise`) and finally reset.

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **Mode** (output_control) string $\leadsto$ *string*
Display mode for images.

Result

`get_comprise` returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`set_comprise`, `disp_image`, `disp_image`

See also

`set_comprise`, `disp_image`, `disp_color`

Module

Foundation

get_fix (: : WindowHandle : Mode)

*Get mode of fixing of current look-up-table (lut).***get_fix** is obsolete and is only provided for reasons of backward compatibility.

Use `get_fix` to get mode of fixing of current look-up-table (look-up-table of valid window) set before by `set_fix`.

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **Mode** (output_control) string $\leadsto$ *string*
Current Mode of fixing.

Result

`get_fix` returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Successors

[set_fix](#), [set_pixel](#), [set_rgb](#)

[set_fix](#)

Module

Foundation

get_fixed_lut (: : WindowHandle : Mode)

Get fixing of “look-up-table” (lut) for “real color images”

get_fixed_lut is obsolete and is only provided for reasons of backward compatibility.

Get fixing of “look-up-table” (lut) for “real color images”

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **Mode** (output_control) string $\leadsto$ *string*
Mode of fixing.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

[set_fixed_lut](#)

Module

Foundation

get_insert (: : WindowHandle : Mode)

Get the current display mode.

get_insert is obsolete and is only provided for reasons of backward compatibility.

`get_insert` returns the display mode of the output window. It is used by operators like [disp_region](#), [disp_line](#), [disp_rectangle1](#), etc. The mode is set with [set_insert](#). Possible values for [Mode](#) can be queried with the operator [query_insert](#).

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **Mode** (output_control) string $\leadsto$ *string*
Display mode.

Result

`get_insert` returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

Foundation

get_line_approx (: : WindowHandle : Approximation)

Get the current approximation error for contour display.

get_line_approx is obsolete and is only provided for reasons of backward compatibility.

`get_line_approx` returns a parameter that controls the approximation error for region contour display in the window. It is used by the operator [disp_region](#). [Approximation](#) controls the polygon approximation for contour display (0 $\Leftrightarrow$ no approximation). [Approximation](#) is only important for displaying the contour of objects, especially if a line style was set with [set_line_style](#).

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **Approximation** (output_control) string $\leadsto$ *integer*
Current approximation error for contour display.

Result

`get_line_approx` returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

[get_region_polygon](#), [set_line_approx](#), [set_line_style](#), [disp_region](#)

Module

Foundation

get_lut_style (: : WindowHandle : Hue, Saturation, Intensity)
--

Get modification parameters of look-up-table (lut).

get_lut_style is obsolete and is only provided for reasons of backward compatibility.

`get_lut_style` returns the values that were set with [set_lut_style](#). Default is:

Hue: 0.0

Saturation 1.0

Intensity 1.0

Parameters

- ▷ **WindowHandle** (input_control) window $\rightsquigarrow$ *handle*
Window handle.
- ▷ **Hue** (output_control) real $\rightsquigarrow$ *real*
Modification of color value.
- ▷ **Saturation** (output_control) real $\rightsquigarrow$ *real*
Modification of saturation.
- ▷ **Intensity** (output_control) real $\rightsquigarrow$ *real*
Modification of intensity.

Result

`get_lut_style` returns 2 (H_MSG_TRUE) if the window is valid and the parameter is correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`set_lut_style`, `set_lut`

See also

`set_lut_style`

Module

Foundation

get_pixel (: : WindowHandle : Pixel)

Get the current color lookup table index.

get_pixel is obsolete and is only provided for reasons of backward compatibility.

`get_pixel` returns the internal coding of the output gray value or color, respectively, for the window. If the output mode is set to color(s) or gray value(s) (see `set_color` or `set_gray`), then the color- or gray values are transformed for internal use. The internal code is then used for (physical) screen display. The transformation depends on the mapping characteristics and the condition of the output device and can be different in different program runs. Don't confuse the term "pixel" with the term "pixel" in image processing (the other operator is `get_grayval`). Here a pixel is meant to be the color lookup table index.

With `get_pixel` it is possible to save the output mode without knowing whether colors or gray values are used. `Pixel` is set with the operator `set_pixel`.

Parameters

- ▷ **WindowHandle** (input_control) window $\rightsquigarrow$ *handle*
Window handle.
- ▷ **Pixel** (output_control) integer-array $\rightsquigarrow$ *integer*
Index of the current color look-up table.

Result

`get_part_style` returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

[set_pixel](#), [disp_region](#), [disp_image](#)

See also

[set_pixel](#)

Module

Foundation

```
get_tshape ( : : WindowHandle : TextCursor )
```

*Get the shape of the text cursor.***get_tshape is obsolete and is only provided for reasons of backward compatibility.**`get_tshape` queries the shape of the text cursor for the output window. A new cursor shape is set by the operator [set_tshape](#).

A text cursor marks the current position for text output (which can also be invisible). It is different from the mouse cursor (although both will be called "cursor" if the context makes misconceptions impossible). The available shapes for the text cursor can be queried with [query_tshape](#).

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **TextCursor** (output_control) string $\leadsto$ *string*
Name of the current text cursor.

Result

`get_tshape` returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
gnuplot_close ( : : GnuplotFileID : )
```

*Close all open gnuplot files or terminate an active gnuplot sub-process.***gnuplot_close is obsolete and is only provided for reasons of backward compatibility.**

`gnuplot_close` closes all gnuplot files opened by [gnuplot_open_file](#) or terminates the gnuplot sub-process created with [gnuplot_open_pipe](#). In the latter case, all temporary files used to display images and control values are deleted. This means that `gnuplot_close` must be called after such a plot sequence. `GnuplotFileID` is the identifier of the corresponding gnuplot output stream.

Parameters

- ▷ **GnuplotFileID** (input_control) gnuplot $\rightsquigarrow$ *handle*
 Identifier for the gnuplot output stream.

Result

gnuplot_close returns 2 (H_MSG_TRUE) if **GnuplotFileID** is a valid gnuplot output stream. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

[gnuplot_open_pipe](#), [gnuplot_open_file](#), [gnuplot_plot_image](#)

Module

Foundation

gnuplot_open_file (: : FileName : GnuplotFileID)

Open a gnuplot file for visualization of images and control values.

gnuplot_open_file is obsolete and is only provided for reasons of backward compatibility.

gnuplot_open_file allows the output of images and control values in a format which can be later processed by gnuplot. The parameter **FileName** determines the base-name of the files to be created by calls to [gnuplot_plot_image](#). **gnuplot_open_file** generates a gnuplot control file with the name **<FileName>.gp**, in which the respective plot commands are written. Each image plotted by [gnuplot_plot_image](#) (or control values plotted by [gnuplot_plot_ctrl](#)) creates a data file with the name **<FileName>.dat.<Number>**, where Number is the number of the plot in the current sequence. The generated control file can later be edited to create the desired effect. After the last plot [gnuplot_close](#) has to be called in order to close all open files. The corresponding identifier for the gnuplot output stream is returned in **GnuplotFileID**.

Parameters

- ▷ **FileName** (input_control) filename.write $\rightsquigarrow$ *string*
 Base name for control and data files.
File extension: .gp
- ▷ **GnuplotFileID** (output_control) gnuplot $\rightsquigarrow$ *handle*
 Identifier for the gnuplot output stream.

Result

gnuplot_open_file returns the value 2 (H_MSG_TRUE) if the control file could be opened. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

[gnuplot_plot_image](#), [gnuplot_close](#)

Alternatives

[gnuplot_open_pipe](#)

[gnuplot_open_pipe](#), [gnuplot_close](#), [gnuplot_plot_image](#)

Module

Foundation

gnuplot_open_pipe (: : : GnuplotFileID)

Open a pipe to a gnuplot process for visualization of images and control values.

gnuplot_open_pipe is obsolete and is only provided for reasons of backward compatibility.

`gnuplot_open_pipe` opens a pipe to a gnuplot sub-process with which subsequently images can be visualized as 3D-plots ([gnuplot_plot_image](#)) or control values can be visualized as 2D-plots ([gnuplot_plot_ctrl](#)). The sub-process must be terminated after displaying the last plot by calling [gnuplot_close](#). The corresponding identifier for the gnuplot output stream is returned in [GnuplotFileID](#).

Attention

`gnuplot_open_pipe` is only implemented for Unix-like systems because gnuplot for Windows (`wgnuplot`) cannot be controlled by an external process.

Parameters

- ▷ **GnuplotFileID** (`output_control`) `gnuplot` $\rightsquigarrow$ *handle*
Identifier for the gnuplot output stream.

Result

`gnuplot_open_pipe` returns the value 2 (`H_MSG_TRUE`) if the sub-process could be created. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

[gnuplot_plot_image](#), [gnuplot_plot_ctrl](#), [gnuplot_close](#)

Alternatives

[gnuplot_open_file](#)

Module

Foundation

gnuplot_plot_ctrl (: : GnuplotFileID, Values :)

Plot control values using gnuplot.

gnuplot_plot_ctrl is obsolete and is only provided for reasons of backward compatibility.

`gnuplot_plot_ctrl` displays a tuple of control values using gnuplot. If there is an active gnuplot sub-process (started with [gnuplot_open_pipe](#)), the image is displayed in a gnuplot window. Otherwise, the image is output to a file, which can be later read by gnuplot. In both cases the gnuplot output stream is identified by [GnuplotFileID](#).

Parameters

- ▷ **GnuplotFileID** (input_control) gnuplot $\leadsto$ *handle*
Identifier for the gnuplot output stream.
- ▷ **Values** (input_control) number-array $\leadsto$ *real* / integer
Control values to be plotted (y-values).

Result

`gnuplot_plot_ctrl` returns the value if `GnuplotFileID` is a valid gnuplot output stream, if the data file for the current plot could be opened, and if only integer or floating point values were passed. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`gnuplot_open_pipe`, `gnuplot_open_file`

Possible Successors

See also

`gnuplot_open_pipe`, `gnuplot_open_file`, `gnuplot_close`

Module

Foundation

gnuplot_plot_func1d (: : GnuplotFileID, Function :)

Plot a function using `gnuplot`.

`gnuplot_plot_func1d` is obsolete and is only provided for reasons of backward compatibility.

`gnuplot_plot_ctrl` displays a function of control values using `gnuplot`. If there is an active `gnuplot` subprocess (started with `gnuplot_open_pipe`), the image is displayed in a `gnuplot` window. Otherwise, the image is output to a file, which can be later read by `gnuplot`. In both cases the `gnuplot` output stream is identified by `GnuplotFileID`.

Parameters

- ▷ **GnuplotFileID** (input_control) gnuplot $\leadsto$ *handle*
Identifier for the gnuplot output stream.
- ▷ **Function** (input_control) function_1d $\leadsto$ *real* / integer
Function to be plotted.

Result

`gnuplot_plot_ctrl` returns 2 (`H_MSG_TRUE`) if `GnuplotFileID` is a valid `gnuplot` output stream, and if the data file for the current plot could be opened. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

<code>gnuplot_open_pipe</code> , <code>gnuplot_open_file</code> , <code>gnuplot_close</code>	
	Module
Foundation	

```
gnuplot_plot_image ( Image : : GnuplotFileID, SamplesX, SamplesY,
                     ViewRotX, ViewRotZ, Hidden3D : )
```

Visualize images using `gnuplot`.

`gnuplot_plot_image` is obsolete and is only provided for reasons of backward compatibility.

`gnuplot_plot_image` displays an image as a 3D-plot using `gnuplot`. If there is an active `gnuplot` sub-process (started with `gnuplot_open_pipe`), the image is displayed in a `gnuplot` window. Otherwise, the image is output to a file, which can be later read by `gnuplot`. In both cases the `gnuplot` output stream is identified by `GnuplotFileID`. The parameters `SamplesX` and `SamplesY` determine the number of data points in the x- and y-direction, respectively, which `gnuplot` should use to display the image. They are the equivalent of the `gnuplot` variables `samples` and `isosamples`. The parameters `ViewRotX` and `ViewRotZ` determine the rotation of the plot with respect to the viewer. `ViewRotX` is the rotation of the coordinate system about the x-axis, while `ViewRotZ` is the rotation of the plot about the z-axis. These two parameters correspond directly to the first two parameters of the 'set view' command in `gnuplot`. The parameter `Hidden3D` determines whether hidden surfaces should be removed. This is equivalent to the 'set hidden3d' command in `gnuplot`. If a single image is passed to the operator, it is displayed in a separate plot. If multiple images are passed, they are displayed in the same plot.

	Parameters
▷ Image (input_object) singlechannelimage $\leadsto$ object : byte / direction / cyclic / int1 / int2 / uint2 / int4 / real	
Image to be plotted.	
▷ GnuplotFileID (input_control) gnuplot $\leadsto$ handle	
Identifier for the <code>gnuplot</code> output stream.	
▷ SamplesX (input_control) integer $\leadsto$ integer	
Number of samples in the x-direction.	
Default: 64	
Value range: $1 \leq \text{SamplesX}$	
▷ SamplesY (input_control) integer $\leadsto$ integer	
Number of samples in the y-direction.	
Default: 64	
Value range: $1 \leq \text{SamplesY}$	
▷ ViewRotX (input_control) number $\leadsto$ real / integer	
Rotation of the plot about the x-axis.	
Default: 60	
Value range: $0 \leq \text{ViewRotX} \leq 180$	
Minimum increment: 0.01	
Recommended increment: 10	
▷ ViewRotZ (input_control) number $\leadsto$ real / integer	
Rotation of the plot about the z-axis.	
Default: 30	
Value range: $0 \leq \text{ViewRotZ} \leq 360$	
Minimum increment: 0.01	
Recommended increment: 10	
▷ Hidden3D (input_control) string $\leadsto$ string	
Plot the image with hidden surfaces removed.	
Default: 'hidden3d'	
List of values: <code>Hidden3D</code> $\in$ {'hidden3d', 'nohidden3d'}	
	Result

`gnuplot_plot_image` returns the value if `GnuplotFileID` is a valid gnuplot output stream, and if the data file for the current plot could be opened. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

move_rectangle (: : WindowHandle, Row1, Column1, Row2, Column2, DestRow, DestColumn :)

Copy inside an output window.

move_rectangle is obsolete and is only provided for reasons of backward compatibility.

`move_rectangle` copies all entries in the rectangle (`Row1,Column1`), (`Row2,Column2`) of the output window to a new position inside the same window. This position is determined by the upper left corner (`DestRow`, `DestColumn`). Regions of the window, which are “uncovered” through moving the rectangle, are set to the color of the background.

If you want to move several rectangles at once, you may pass parameters in form of tuples.

Parameters

- ▷ **WindowHandle** (input_control) window $\rightsquigarrow$ *handle*
Window handle.
- ▷ **Row1** (input_control) rectangle.origin.y(-array) $\rightsquigarrow$ *integer*
Row index of upper left corner of the source rectangle.
Default: 0
Value range: $0 \leq \text{Row1} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Column1** (input_control) rectangle.origin.x(-array) $\rightsquigarrow$ *integer*
Column index of upper left corner of the source rectangle.
Default: 0
Value range: $0 \leq \text{Column1} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Row2** (input_control) rectangle.corner.y(-array) $\rightsquigarrow$ *integer*
Row index of lower right corner of the source rectangle.
Default: 64
Value range: $0 \leq \text{Row2} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Column2** (input_control) rectangle.corner.x(-array) $\rightsquigarrow$ *integer*
Column index of lower right corner of the source rectangle.
Default: 64
Value range: $0 \leq \text{Column2} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1

- ▷ **DestRow** (input_control) point.y(-array) $\leadsto$ *integer*
 Row index of upper left corner of the target position.
Default: 64
Value range: $0 \leq \text{DestRow} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **DestColumn** (input_control) point.x(-array) $\leadsto$ *integer*
 Column index of upper left corner of the target position.
Default: 64
Value range: $0 \leq \text{DestColumn} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1

Example

```
* "Interactive" copy of a rectangle in the same window
draw_rectangle1 (WindowHandle, L1, C1, L2, C2)
get_mbutton (WindowHandle, LN, CN, Button)
move_rectangle (WindowHandle, L1, C1, L2, C2, LN, CN)
```

Result

If the window is valid and the specified parameters are correct `move_rectangle` returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[open_window](#)

Alternatives

[copy_rectangle](#)

See also

[open_window](#)

Module

Foundation

```
open_textwindow ( : : Row, Column, Width, Height, BorderWidth,
  BorderColor, BackgroundColor, FatherWindow, Mode,
  Machine : WindowHandle )
```

Open a textual window.

open_textwindow is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator [open_window](#) instead.

`open_textwindow` opens a new textual window, which can be used to perform textual input and output, as well as to perform output of images. All output ([write_string](#), [read_string](#), [disp_region](#), etc.) is redirected to this window, if the same logical window number `WindowHandle` is used.

Besides the mouse cursor textual windows possess also a textual cursor which indicates the current writing position (more exactly: the lower left corner of the output string without consideration of descenders). Its position is indicated through an underscore or another type (the indication of this position may also be disabled (= default setting); cf. [set_tshape](#)). You may set or query the position by calling the operators [set_tposition](#) or [get_tposition](#).

After you opened a textual window the position of the cursor is set to (H,0). Whereby H signifies the height of the default font less the descenders. But the cursor is not shown. Hence the output starts for writing in the upper left corner of the window.

You may query the colors of the background and the image edges by calling `query_color`. In the same way you may use `query_color` in a window of type 'invisible'. During output (`write_string`) you may set the clipping of text out of the window edges by calling `set_check(:,:, 'text')`. This disables the creation of error messages, if text passes over the edge of the window.

The origin of the coordinate system of the window resides in the upper left corner (coordinates: (0,0)). The row index grows downward (maximal: `Height-1`), the column index grows to the right (maximal: `Width-1`).

The parameter `Machine` indicates the name of the computer, which has to open the window. In case of a X-window, TCP-IP only sets the name, DEC-Net sets in addition a colon behind the name. The "server" or the "screen", respectively, are not specified. If the empty string is passed the environment variable DISPLAY is used. It indicates the target computer. At this the name is indicated in common syntax

```
<Host>:0.0
```

.

For windows of type 'WIN32-Window' and 'X-Window' the parameter `FatherWindow` can be used to determine the father window for the window to be opened. In case the control 'father' is set via `set_check`, `FatherWindow` must be the ID of a HALCON window, otherwise (`set_check(:,:, 'father')`) it can also be the ID of an operating system window. If `FatherWindow` is passed the value 0 or 'root', then under Windows and Unix-like systems the desktop and the root window become the father window, respectively. In this case, the value of the control 'father' (set via `set_check`) is irrelevant. The caller must ensure that `FatherWindow` is a valid handle and not destroyed as long as the embedded HALCON window is used.

Position and size of a window may change during runtime of a program. This may be achieved by calling `set_window_extents`, but also through external interferences (window manager). In the latter case the operator `set_window_extents` is provided.

Opening a window causes the assignment of a called default font. It is used in connection with operators like `write_string` and you may overwrite it by performing `set_font` after calling `open_textwindow`. On the other hand you have the possibility to specify a default font by calling `set_system(:,:, 'default_font', <Fontname>:)` before opening a window (and all following windows; see also `query_font`).

You may set the color of the font (`write_string`, `read_string`) by calling `set_color`, `set_rgb`, `set_hsi` or `set_gray`. Calling `set_insert` specifies how the text or the graphics, respectively, is combined with the content of the image repeat memory. So you may achieve by calling, e.g., `set_insert(:,:, 'not')` to eliminate the font after writing text twice at the same position.

Normally every output (e.g., `write_string`, `disp_region`, `disp_circle`, etc.) in a window is terminated by a "flush". This causes the data to be fully visible on the display after termination of the output operator. But this is not necessary in all cases, in particular if there are permanently output tasks or there is a mouse procedure active. Therefore it is more favorable (i.e., more rapid) to store the data until sufficient data is available. You may stop this behavior by calling `set_system(:,:, 'flush_graphic', 'false')`.

The content of windows is saved (in case it is supported by special driver software); i.e., it is preserved, also if the window is hidden by other windows. But this is not necessary in all cases: If you use a textual window, e.g., as a parent window for other windows, you may suppress the security mechanism for it and save the necessary memory at the same moment. You achieve this before opening the window by calling `set_system(:,:, 'backing_store', 'false')`.

Difference: graphical window - textual window

- In contrast to graphical windows (`open_window`) you may specify more parameters (color, edge) for a textual window while opening it.
- You may use textual windows only for input of user data (`read_string`).
- Using textual windows, the output of images, regions and graphics is "clipped" at the edges. Whereas during the use of graphical windows the edges are "zoomed".
- The coordinate system (e.g., with `get_mbutton` or `get_mposition`) consists of display coordinates independently of image size. The maximum coordinates are equal to the size of the window minus 1. In contrast to this, graphical windows (`open_window`) use always a coordinate system, which corresponds to the image format.

The parameter `Mode` specifies the mode of the window. It can have following values:

- 'visible':** Normal mode for textual windows: The window is created according to the parameters and all inputs and outputs are possible.
- 'invisible':** Invisible windows are not displayed in the display. Parameters like `Row`, `Column`, `BorderWidth`, `BorderColor`, `BackgroundColor` and `FatherWindow` do not have any meaning. Output to these windows has no effect. Input (`read_string`, mouse, etc.) is not possible. You may use these windows to query representation parameter for an output device without opening a (visible) window. General queries are, e.g., `query_color` and `get_string_extents`.
- 'transparent':** These windows are transparent: the window itself is not visible (edge and background), but all the other operations are possible and all output is displayed. Parameters like `BorderColor` and `BackgroundColor` do not have any meaning. A common use for this mode is the creation of mouse sensitive regions.
- 'buffer':** These are also not visible windows. The output of images, regions and graphics is not visible on the display, but is stored in memory. Parameters like `Row`, `Column`, `BorderWidth`, `BorderColor`, `BackgroundColor` and `FatherWindow` do not have any meaning. You may use buffer windows, if you prepare output (in the background) and copy it finally with `copy_rectangle` in a visible window. Another usage might be the rapid processing of image regions during interactive manipulations. Textual input and mouse interaction are not possible in this mode.

Attention

You have to keep in mind that parameters like `Row`, `Column`, `Width` and `Height` are restricted by the output device. Is a father window (`FatherWindow <> 'root'`) specified, then the coordinates are relative to this window.

Parameters

- ▷ **Row** (input_control)rectangle.origin.y $\leadsto$ *integer*
Row index of upper left corner.
Default: 0
(lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Column** (input_control)rectangle.origin.x $\leadsto$ *integer*
Column index of upper left corner.
Default: 0
(lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Width** (input_control)rectangle.extent.x $\leadsto$ *integer*
Window's width.
Default: 256
Value range: $0 \leq \text{Width (lin)}$
Minimum increment: 1
Recommended increment: 1
- ▷ **Height** (input_control)rectangle.extent.y $\leadsto$ *integer*
Window's height.
Default: 256
Value range: $0 \leq \text{Height (lin)}$
Minimum increment: 1
Recommended increment: 1
- ▷ **BorderWidth** (input_control) integer $\leadsto$ *integer*
Window border's width.
Default: 2
Value range: $0 \leq \text{BorderWidth (lin)}$
Minimum increment: 1
Recommended increment: 1
- ▷ **BorderColor** (input_control)string $\leadsto$ *string*
Window border's color.
Default: 'white'

- ▷ **BackgroundColor** (input_control) string $\leadsto$ string
Background color.
Default: 'black'
- ▷ **FatherWindow** (input_control) pointer $\leadsto$ integer / string
Logical number of the father window. For the display as father you may specify 'root' or 0.
Default: 0
Restriction: FatherWindow $\geq$ 0
- ▷ **Mode** (input_control) string $\leadsto$ string
Window mode.
Default: 'visible'
List of values: Mode $\in$ {'visible', 'invisible', 'transparent', 'buffer'}
- ▷ **Machine** (input_control) string $\leadsto$ string
Computer name, where the window has to be opened or empty string.
Default: ''
- ▷ **WindowHandle** (output_control) window $\leadsto$ handle
Window handle.

Example

```
open_textwindow(0,0,900,600,1,'black','slate blue','root','visible', \
                '',WindowHandle1)
open_textwindow(10,10,300,580,3,'red','blue',WindowHandle1,'visible', \
                '',WindowHandle2)
open_window(10,320,570,580,WindowHandle1,'visible','',WindowHandle)
set_color(WindowHandle,'red')
read_image(Image,'monkey')
disp_image(Image,WindowHandle)
Button := 0
repeat
  try
    get_mposition(WindowHandle,Row,Column,Button)
    get_grayval(Image,Row,Column,Gray)
    write_string(WindowHandle2,[' Position (',Row,',',',',Column,',')  '])
    write_string(WindowHandle2,['Gray value (',Gray,',')  '])
    new_line(WindowHandle2)
  catch (Exception)
  endtry
until(Button == 4)
close_window(WindowHandle1)
```

Result

If the values of the specified parameters are correct `open_textwindow` returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

query_insert (: : WindowHandle : Mode)

Query the possible graphic modes.

query_insert is obsolete and is only provided for reasons of backward compatibility.

`query_insert` returns the possible modes pixels can be displayed in the output window. New pixels may e.g., overwrite old ones. In most of the cases there is a functional relationship between old and new values.

Possible display functions:

'copy': overwrite displayed pixels

'xor': display old “xor” new pixels

'complement': complement displayed pixels

“copy” is always available.

Parameters

- ▷ **WindowHandle** (input_control) window $\rightsquigarrow$ handle
Window handle.
- ▷ **Mode** (output_control) string-array $\rightsquigarrow$ string
Display function name.

Result

`query_insert` returns 2 (H_MSG_TRUE), if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

query_tshape (: : WindowHandle : TextCursor)

Query all shapes available for text cursors.

query_tshape is obsolete and is only provided for reasons of backward compatibility.

`query_tshape` queries the available shapes of text cursors for the output window. The retrieved shapes can be used by the operator [set_tshape](#).

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **TextCursor** (output_control) string-array $\leadsto$ *string*
Names of the available text cursors.

Result

query_tshape returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_comprise (: : WindowHandle, Mode :)

Define the image matrix output clipping.

set_comprise is obsolete and is only provided for reasons of backward compatibility.

set_comprise defines the image matrix output clipping. If [Mode](#) is set to 'object', only gray values belonging to the output object are displayed. If set to 'image', the whole image matrix is displayed. Default is 'object'.

Attention

If [Mode](#) was set to 'image', undefined gray values may be displayed. Depending on the context they are black or can have random content. See the examples.

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **Mode** (input_control) string $\leadsto$ *string*
Clipping mode for gray value output.
Default: 'object'
List of values: Mode $\in$ {'image', 'object'}

Example

```
read_image (Image, 'fabrik')
gen_circle (Circle, 200, 200, 100.5)
reduce_domain (Image, Circle, ImageReduced)
set_system ('init_new_image', 'false')
sobel_amp (ImageReduced, SobelReduced, 'sum_abs', 3)
dev_display (SobelReduced)
get_comprise (WindowHandle, Mode)
set_comprise (WindowHandle, 'image')
stop ()
dev_display (SobelReduced)
```

Result

`set_comprise` returns 2 (H_MSG_TRUE) if `Mode` is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_fix (: : WindowHandle, Mode :)

Set fixing of “look-up-table” (*lut*)

set_fix is obsolete and is only provided for reasons of backward compatibility.

Behavior for `Mode = 'true'`: `set_fix` fixes that pixel lastly ascertained by one of the operators `set_gray`, `set_color`, `set_hsi` or `set_rgb` (Remark: Here a pixel is the index within the current look-up-table). To assign a new color to a fixed pixel set a color or gray value by using `set_color`, `set_rgb`, `set_hsi` or `set_gray`. This makes it possible to define any color (`set_color`), any gray value (`set_gray`) and any color combination (`set_rgb`, `set_hsi`) at any position of the look-up-table.

`Mode` set to 'false' reset the fixing. To modify or create a look-up-table process `set_pixel`, `set_fix (:: WindowHandle, 'true' :)`, `set_rgb` and `set_fix (:: WindowHandle, 'false' :)` one after another.

Attention

As a side effect `set_fix` can change colors of “non-HALCON windows”.

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ handle
Window handle.
- ▷ **Mode** (input_control) string $\leadsto$ string
Mode of fixing.
Default: 'true'
List of values: `Mode` $\in$ {'true', 'false'}

Result

`set_fix` returns 2 (H_MSG_TRUE) if the window is valid, the hardware supports a look-up-table and all parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_fixed_lut (: : WindowHandle, Mode :)

Fix “look-up-table” (lut) for “real color images”.

set_fixed_lut is obsolete and is only provided for reasons of backward compatibility.

Fix “look-up-table” (lut) for “real color images”.

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ handle
Window handle.
- ▷ **Mode** (input_control) string $\leadsto$ string
Mode of fixing.
Default: 'true'
List of values: Mode $\in$ {'true', 'false'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[get_fixed_lut](#)

Module

Foundation

set_insert (: : WindowHandle, Mode :)
--

Define the pixel output function.

set_insert is obsolete and is only provided for reasons of backward compatibility.

`set_insert` defines the function, with which pixels are displayed in the output window. It is e.g., possible for a pixel to overwrite the old value. In most of the cases there is a functional relationship between old and new values. The definition value is only valid for the valid window. Output operators that honor [Mode](#) are e.g., [disp_region](#), [disp_polygon](#), [disp_circle](#).

Possible display functions are:

- 'copy':** overwrite displayed pixels
- 'xor':** display old "xor" new pixels
- 'complement':** complement displayed pixels

There may not be all functions available, depending on the physical display. However, “copy” is always available.

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ handle
Window handle.
- ▷ **Mode** (input_control) string $\leadsto$ string
Name of the display function.
Default: 'copy'
List of values: Mode $\in$ {'copy', 'xor', 'complement'}

Result

`set_insert` returns 2 (H_MSG_TRUE) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_line_approx (: : WindowHandle, Approximation :)
--

Define the approximation error for contour display.

set_line_approx is obsolete and is only provided for reasons of backward compatibility.

`set_line_approx` defines the approximation error for region and xld contour display in the window `WindowHandle`. `Approximation` values greater than zero cause an approximation of line strokes using less points. This may enable faster and in some cases smoother visualization. The parameter describes the maximal deviation in pixels of the approximated contour from the original contour (Ramer-Douglas-Peucker algorithm).

Parameters

- ▷ **WindowHandle** (input_control) window $\rightsquigarrow$ handle
Window handle.
- ▷ **Approximation** (input_control) integer $\rightsquigarrow$ integer
Maximum deviation from the original contour.
Default: 0
Value range: $0 \leq \text{Approximation}$

Example

```
* Calling...
set_line_approx(WindowHandle, Approximation)
set_draw(WindowHandle, 'margin')
disp_region(Obj, WindowHandle)

* ...corresponds with
get_region_polygon(Obj, Approximation, Row, Col)
disp_polygon(WindowHandle, Row, Col)
```

Result

`set_line_approx` returns 2 (H_MSG_TRUE) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

set_lut_style (: : WindowHandle, Hue, Saturation, Intensity :)

Changing the look-up-table (lut).

set_lut_style is obsolete and is only provided for reasons of backward compatibility.

`set_lut_style` changes the look-up-table (lut) of the device displaying the valid output window. It has got three parameters:

Hue: Rotation of color space, Hue = 1.9 conforms to a one-time rotation of the color space. No changes: Hue = 0.0 Complement colors: Hue = 0.5

Saturation: Changes of saturation, No changes: Saturation = 1.0 Gray value image: Saturation = 0.0

Intensity: Changes of intensity, No changes: Intensity = 1.0 Black image: Intensity = 0.0

Changes affect only the part of an look-up-table that is used for displaying images. The parameter of modification remain until the next call of `set_lut_style`. Calling `set_lut` has got no effect on these parameters.

	Parameters
▷ WindowHandle (input_control)	window $\rightsquigarrow$ handle
Window handle.	
▷ Hue (input_control)	real $\rightsquigarrow$ real
Modification of color value.	
Default: 0.0	
Value range: $0.0 \leq \text{Hue} \leq 1.0$	
▷ Saturation (input_control)	real $\rightsquigarrow$ real
Modification of saturation.	
Default: 1.5	
Value range: $0.0 \leq \text{Saturation}$	
▷ Intensity (input_control)	real $\rightsquigarrow$ real
Modification of intensity.	
Default: 1.5	
Value range: $0.0 \leq \text{Intensity}$	

	Example
--	---------

```
read_image (Image, 'monkey')
dev_set_lut ('color1')
repeat
  get_mbutton (WindowHandle, Row, Column, Button)
  Saturation := Row/300.0
  Hue := Column/512.0
  set_lut_style (WindowHandle, Hue, Saturation, 1.0)
  dev_display (Image)
until (Button == 4)
```

Result

`set_lut_style` returns 2 (H_MSG_TRUE) if the window is valid and the parameter is correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`get_lut_style`

Possible Successors

`set_lut`

Alternatives

`set_lut, scale_image`

See also

`get_lut_style`

Module

Foundation

set_pixel (: : WindowHandle, Pixel :)
--

Define a color lookup table index.

set_pixel is obsolete and is only provided for reasons of backward compatibility.

`set_pixel` sets pixel values: colors (`set_color`, `set_rgb`, etc.) and gray values (`set_gray`) are coded together into a number, called pixel. This 'pixel' is an index in the color lookup table. It ranges from 0 to 1 in b/w images and 0 to 255 color images with 8 bit planes. It is different from the 'pixel' ("picture element") in image processing. Therefore HALCON distinguishes between pixel and image element (or gray value).

The current value can be queried with `get_pixel`.

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ handle
Window handle.
- ▷ **Pixel** (input_control) integer(-array) $\leadsto$ integer
Color lookup table index.
Default: 128
Value range: $0 \leq \text{Pixel} \leq 255$

Result

`set_pixel` returns 2 (H_MSG_TRUE) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

set_tshape (: : WindowHandle, TextCursor :)

Set the shape of the text cursor.

set_tshape is obsolete and is only provided for reasons of backward compatibility.

set_tshape sets the shape and the display mode of the text cursor of the output window.

A text cursor marks the current position for text output. It is different from the mouse cursor (although both will be called 'cursor', if the context makes misconceptions impossible). The available shapes for the text cursor can be queried with [query_tshape](#).

Parameters

- ▷ **WindowHandle** (input_control) window $\leadsto$ *handle*
Window handle.
- ▷ **TextCursor** (input_control) string $\leadsto$ *string*
Name of cursor shape.
Default: 'invisible'

Result

set_tshape returns 2 (H_MSG_TRUE) if the window is valid and the given cursor shape is defined for this window. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

slide_image (: : WindowHandleSource1, WindowHandleSource2,
WindowHandle :)

Interactive output from two window buffers.

The operator slide_image does not work with HDevelop graphics windows. It is only provided for reasons of backward compatibility.

slide_image divides the window horizontal in two logical areas dependent of the mouse position. The content of the first indicated window is copied in the upper area, the content of the second window is copied in the lower area. If you press the left mouse button you may scroll the delimitation between the two areas (you may move the mouse outside the window, too. In doing so the position of the mouse relative to the window determines the borderline).

Pressing the right mouse button in the window terminates the operator slide_image.

A useful application of the operator `slide_image` might be the visualization of the effect of a filtering operation for an image. The output is directed to the currently set window ([WindowHandle](#)).

Attention

The three windows must have the same size and have to reside on the same computer.

Parameters

- ▷ **WindowHandleSource1** (input_control) window $\leadsto$ handle
Source window handle of the “upper window”.
- ▷ **WindowHandleSource2** (input_control) window $\leadsto$ handle
Source window handle of the “lower window”.
- ▷ **WindowHandle** (input_control) window $\leadsto$ handle
Output window handle.

Example

```
read_image (Image, 'fabrik')
sobel_dir (Image, EdgeAmplitude, EdgeDirection, 'sum_abs', 3)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle1)
dev_display (EdgeAmplitude)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle2)
dev_display (EdgeDirection)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
slide_image (WindowHandle1, WindowHandle2, WindowHandle)
```

Result

If the both windows exist and one of these windows is valid `slide_image` returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

write_lut (: : WindowHandle, FileName :)

Write look-up-table (lut) as file.

write_lut is obsolete and is only provided for reasons of backward compatibility.

`write_lut` saves the look-up-table (resp. the part of it that is relevant for displaying image gray values) of the valid output window into a file named '[FileName.lut](#)'. It can be read again later with [set_lut](#).

Attention

`write_lut` is only suitable for systems using 256 colors.

Parameters

- ▷ **WindowHandle** (input_control) window $\rightsquigarrow$ *handle*
Window handle.
- ▷ **FileName** (input_control) filename.write $\rightsquigarrow$ *string*
File name (of file containing the look-up-table).
Default: '/tmp/lut'
File extension: .lut

Result

write_lut returns 2 (H_MSG_TRUE) if the window with the required properties (256 colors) is valid and the parameter (file name) is correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

17.8 Identification

This chapter contains operators for sample-based identification.

Concept of sample-based identification

With sample-based identification, trained objects can be identified based on characteristic features like texture or color. This allows you to identify objects that do not carry bar codes or data codes. Compared to the classification approaches described in chapter [Classification](#), the preparation and training for sample-based identification is very convenient as no complex parameter tuning is required. Sample-based identification is capable of differentiating a large number of objects. The identification is robust against rotation, scale, and illumination changes as well as against occlusions, clutter, and moderate perspective distortions. Furthermore, the identification is robust against moderate deformations of the object and, within certain limits, it even allows to identify products stored in bulk. On the other hand, this means that objects cannot be distinguished if they appear identical except for one of the characteristics the identification is robust against. Note that sample-based identification works only with textured objects.

Sample-based identification can identify only one object at the same time. This means that each query image, or more precisely the domain of each query image, must not contain multiple objects.

(1)

(2)

(3)

(4)

Sample-based identification of the objects 'potato', 'blueberry', 'arugula', and 'champignon'. These images are from the example program `identify_vegetables.hdev`.

In the following, the steps that are required to use sample-based identification are described briefly.

Create and prepare a sample identifier: First, a sample identifier must be provided by creating and preparing a new sample identifier with

- `create_sample_identifier`,
- `add_sample_identifier_preparation_data`, and
- `prepare_sample_identifier`.

The preparation is essential to adapt the internal data structure of the sample identifier to the kind of objects to be identified. Alternatively, an already prepared sample identifier, which has been written to file with `write_sample_identifier`, can be read from file with `read_sample_identifier`.

A prepared sample identifier can be thought of as a warehouse, optimized to handle a specific group of objects.

Train sample identifier: Then, the prepared sample identifier has to be trained with samples of the individual objects to be identified. For this, the operators

- `add_sample_identifier_training_data` and
- `train_sample_identifier`

are used. Note that it is possible to retrain the sample identifier at any time. For this, samples can be removed from the sample identifier with the operator `remove_sample_identifier_training_data` and new samples can be added to the sample identifier with the operator `add_sample_identifier_training_data`. If the kind of the objects to be identified does not change too much, it is not necessary to repeat the preparation of the sample identifier. To use the picture from above, the training corresponds to filling the warehouse.

Apply sample identifier to identify objects: Finally, the trained sample identifier can be applied to identify objects with

- `apply_sample_identifier`.

Further operators to administrate and control sample identifiers

In addition to the operators mentioned above, the following operators can be used to administrate the sample identifier. With `remove_sample_identifier_preparation_data` the data that were added to the sample identifier can be removed in order to exclude them from being used for the preparation. The operators `set_sample_identifier_object_info` and `get_sample_identifier_object_info` can be used to assign and query labels, i.e., names, to the individual objects. The latter operator can further be used to determine some additional information about the number of objects available for preparation and training. Finally, the operators `set_sample_identifier_param` and `get_sample_identifier_param` can be used to set and retrieve control parameters of the sample identifier.

Glossary

In the following, the most important terms that are used in the context of sample-based identification are described:

object An object to be identified by sample-based identification.

object index The index of an object. This index can be seen as a label of the object, which is set while adding preparation data or training data to the `SampleIdentifier`. The object index is the most important result of the operator `apply_sample_identifier`. With the operator `set_sample_identifier_object_info`, a descriptive name can be set for each object, which eases the interpretation of the identification results.

object sample One sample or view of an object. Sometimes, also the term “sample image” is used to refer to object samples.

sample image This term is used as a synonym for “object sample”, if the emphasis lies on the image.

object sample index The index of an object sample. Note that for each object, this index is set individually starting with 0. Therefore, the object sample index is unambiguous only together with the respective object index.

preparation The adaptation of the internal data structure of the sample identifier to the features of a typical set of object samples that may appear during the identification process.

preparation object An object that has been added to the sample identifier with `add_sample_identifier_preparation_data`.

preparation sample An object sample of a preparation object. The preparation is typically done based on multiple preparation samples per object.

preparation data The collection of all preparation samples.

training The training of the sample identifier. In this step, the sample identifier learns to differentiate all given objects.

training object An object that has been added to the sample identifier with `add_sample_identifier_training_data` or which is the result of reusing preparation data as training data. In contrast to preparation objects, all training objects are labeled with a unique object index.

training sample An object sample of a training object. The training is typically done based on multiple training samples per object.

training data The collection of all training samples.

query image An image, in which an object is visible that should be identified with sample-based identification.

```
add_sample_identifier_preparation_data (
    SampleImage : : SampleIdentifier, ObjectIdx, GenParamName,
    GenParamValue : ObjectSampleIdx )
```

Add preparation data to an existing sample identifier.

add_sample_identifier_preparation_data is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

add_sample_identifier_preparation_data adds preparation data to an existing sample identifier. This is a prerequisite for the preparation of the sample identifier with the operator [prepare_sample_identifier](#).

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

To achieve the maximum identification rate, the internal data structure of the sample identifier must be adapted to the objects to be identified. For this, it is useful to provide sample images of all kinds of objects to be identified.

With each call of add_sample_identifier_preparation_data, features of one [SampleImage](#) are added to the [SampleIdentifier](#). The complete preparation data, which consists of all features of all sample images that have been added to the sample identifier with multiple calls of add_sample_identifier_preparation_data, should cover

- all kinds of objects to be identified and
- all different views of the objects that may appear during the identification process, sampled to at least 45 degrees.

The domain of the [SampleImage](#) should be reduced to the object, which is visible in the image. This is necessary to avoid that the [SampleIdentifier](#) is adapted to the background of the sample images.

If you cannot provide preparation data that fulfills all of the above mentioned requirements, the sample identifier may be prepared as well, but the identification rate may be slightly worse.

Note that you must provide RGB color images, if the generic parameter 'add_color_info' has been set to 'true' in [create_sample_identifier](#).

Ideally, the images used for preparation and training (see [add_sample_identifier_training_data](#) and [train_sample_identifier](#)) are identical. This can easily be realized by reusing the preparation data for the training of the [SampleIdentifier](#). To be able to reuse the preparation data, the index of the object must be given in [ObjectIdx](#). Otherwise, the [ObjectIdx](#) can be set to 'unknown'. See [prepare_sample_identifier](#) for an explanation on how to reuse preparation data for the training of the sample identifier.

The following generic parameters can be used to influence the behavior of the operator add_sample_identifier_preparation_data. These parameters and their corresponding values can be specified by using [GenParamName](#) and [GenParamValue](#), respectively. The following values for [GenParamName](#) are possible:

'image_resize_method': See [create_sample_identifier](#) for a description of this parameter.

List of values: 'none', 'scale_factor', 'subsampling_step', 'image_area'

Default value: If the 'image_resize_method' is not set explicitly by this operator, the value that has been set with [create_sample_identifier](#) or [set_sample_identifier_param](#) will be used.

'image_resize_value': See [create_sample_identifier](#) for a description of this parameter.

Suggested values: 0.25, 0.5, 1.0, 2, 3, 4

Default value: If the 'image_resize_value' is not set explicitly by this operator, the value that has been set with [create_sample_identifier](#) or [set_sample_identifier_param](#) will be used.

add_sample_identifier_preparation_data returns the object sample index of the preparation sample given in [SampleImage](#). This index can, e.g., be used to remove this sample from the preparation data, if the sample identifier should be prepared based on a different set of preparation data.

Parameters

- ▷ **SampleImage** (input_object) (multichannel-)image $\leadsto$ *object* : byte
Image that shows an object.
- ▷ **SampleIdentifier** (input_control) sample_identifier $\leadsto$ *handle*
Handle of the sample identifier.
- ▷ **ObjectIdx** (input_control) integer $\leadsto$ *integer* / string
Index of the object visible in the [SampleImage](#).
Default: 'unknown'
Suggested values: ObjectIdx $\in$ {'unknown', 0, 1, 2, 3, 4, 5}
- ▷ **GenParamName** (input_control) attribute.name-array $\leadsto$ *string*
Generic parameter name.
Default: []
List of values: GenParamName $\in$ {'image_resize_method', 'image_resize_value'}
- ▷ **GenParamValue** (input_control) attribute.value-array $\leadsto$ *real* / *string* / *integer*
Generic parameter value.
Default: []
Suggested values: GenParamValue $\in$ {'none', 'scale_factor', 'subsampling_step', 'image_area', 0.25, 0.5, 0.75, 1.0, 2, 3, 4}
- ▷ **ObjectSampleIdx** (output_control) integer $\leadsto$ *integer*
Index of the object sample.

Result

If the parameters are valid, the operator `add_sample_identifier_preparation_data` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

```
add_sample_identifier_training_data (
    SampleImage : : SampleIdentifier,  ObjectIdx,  GenParamName,
    GenParamValue :  ObjectSampleIdx )
```

Add training data to an existing sample identifier.

add_sample_identifier_training_data is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

`add_sample_identifier_training_data` adds training data to an existing sample identifier. This is a prerequisite for the training of the sample identifier with the operator `train_sample_identifier`.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

In order to be able to identify objects, the `SampleIdentifier` must be trained with a representative set of sample images of the objects to be identified. These sample images must be added to the `SampleIdentifier` with `add_sample_identifier_training_data`.

With each call of `add_sample_identifier_training_data`, one `SampleImage` is added to the `SampleIdentifier`. The complete training data, which consists of all the sample images that have been added to the sample identifier with multiple calls of `add_sample_identifier_training_data`, must cover

- all objects to be identified and
- all different views of the objects that may appear during the identification process, sampled to at least 45°.

The domain of the `SampleImage` should be reduced to the object, which is visible in the image. This is necessary to avoid that the `SampleIdentifier` is trained to the background of the sample images.

Note that in contrast to the preparation data, it is essential that the requirements mentioned above are fulfilled. Otherwise, the sample identifier will not be able to identify the objects for which relevant sample images are missing.

Also note that you must provide RGB color images, if the generic parameter `'add_color_info'` has been set to `'true'` in `create_sample_identifier`.

Ideally, the images used for preparation and training (see `add_sample_identifier_preparation_data` and `prepare_sample_identifier`) are identical. See `prepare_sample_identifier` for an explanation on how to reuse preparation data for the training of the sample identifier.

The following generic parameters can be used to influence the behavior of the operator `add_sample_identifier_training_data`. These parameters and their corresponding values can be specified by using `GenParamName` and `GenParamValue`, respectively. The following values for `GenParamName` are possible:

'image_resize_method': See `create_sample_identifier` for a description of this parameter.

List of values: `'none'`, `'scale_factor'`, `'subsampling_step'`, `'image_area'`

Default value: If the `'image_resize_method'` is not set explicitly by this operator, the value that has been set with `create_sample_identifier` or `set_sample_identifier_param` will be used.

'image_resize_value': See `create_sample_identifier` for a description of this parameter.

Suggested values: `0.25`, `0.5`, `1.0`, `2`, `3`, `4`

Default value: If the `'image_resize_value'` is not set explicitly by this operator, the value that has been set with `create_sample_identifier` or `set_sample_identifier_param` will be used.

`add_sample_identifier_training_data` returns the object sample index of the training sample given in `SampleImage`. This index can, e.g., be used to remove this sample from the training data, if the sample identifier should be retrained based on a different set of training data.

Parameters

- ▷ **SampleImage** (input_object) (multichannel-)image $\leadsto$ object : byte
Image that shows an object.
- ▷ **SampleIdentifier** (input_control) sample_identifier $\leadsto$ handle
Handle of the sample identifier.
- ▷ **ObjectIdx** (input_control) integer $\leadsto$ integer / string
Index of the object visible in the `SampleImage`.
Suggested values: `ObjectIdx` $\in$ {0, 1, 2, 3, 4, 5}
- ▷ **GenParamName** (input_control) attribute.name-array $\leadsto$ string
Generic parameter name.
Default: []
List of values: `GenParamName` $\in$ {'image_resize_method', 'image_resize_value'}

- ▷ **GenParamValue** (input_control)attribute.value-array $\leadsto$ real / string / integer
Generic parameter value.
Default: []
Suggested values: GenParamValue $\in$ {'none', 'scale_factor', 'subsampling_step', 'image_area', 0.25, 0.5, 0.75, 1.0, 2, 3, 4}
- ▷ **ObjectSampleIdx** (output_control)integer $\leadsto$ integer
Index of the object sample.

Result

If the parameters are valid, the operator `add_sample_identifier_training_data` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

```
apply_sample_identifier ( Image : : SampleIdentifier, NumResults,
                          RatingThreshold, GenParamName, GenParamValue : ObjectIdx, Rating )
```

Identify objects with a sample identifier.

`apply_sample_identifier` is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

`apply_sample_identifier` identifies the object in the `Image` using the given `SampleIdentifier` and returns the corresponding `ObjectIdx`.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

The operator `apply_sample_identifier` can identify one object per query `Image`. This means that the `Image`, or more precisely the domain of the `Image`, must not contain multiple objects. The parameter `NumResults` defines the number of hypotheses that are returned, ordered by their rating value. If the generic parameter '`apply_rating_threshold`' is set to '`true`' (see below), all returned hypotheses have a rating value better than the specified `RatingThreshold`.

The index of the identified object is returned in `ObjectIdx` and its rating value is returned in `Rating`. If `NumResults` is set to a value larger than 1, the indices and ratings of the best rated `NumResults` hypotheses are returned in `ObjectIdx` and `Rating`.

The following generic parameters can be used to influence the behavior of the `SampleIdentifier`. These parameters and their corresponding values can be specified by using `GenParamName` and `GenParamValue`, respectively. The following values for `GenParamName` are possible:

'rating_method': This parameter determines, which rating method is used for the identification of the objects. There are three different methods available:

'distance' The rating is based on the distance between the features of the image of the object to be identified and the trained sample images. The rating values lie between 0.0 and 2.0. If the images are identical, a rating value of 0.0 will be returned in `Rating`. The more different the images are, the higher the rating value will be. With this rating method, the raw internal rating is returned. This rating has the advantage that the rating value is independent of training samples other than that of the identified object.

'score' The rating is based on an elaborate combination of the scores for texture and color. The rating values lie between 0.0 and 1.0. Higher rating values indicate more similar images. If both texture and color are used, this rating method yields the best identification results and should therefore be used. One drawback of this rating method is that the rating value of a training image is typically far below 1.0. Furthermore, a suitable threshold must be determined for each application individually.

'score_single' The rating is based on a simple combination of the scores for texture and color. The rating values lie between 0.0 and 1.0. Higher rating values indicate more similar images. If both texture and color are used, the rating method **'score'** yields better results. The advantage of the rating method **'score_single'** is, that it yields a rating value of 1.0 for training images. Therefore, this rating method should be used if only texture or only color is used for the identification. For this rating method, it is much simpler to select a suitable threshold than for the rating method **'score'**.

Note that the selection of the rating method influences both the identification of the objects, i.e., their discrimination, as well as the rating value that is returned in the parameter `Rating`.

List of values: **'distance'**, **'score'**, **'score_single'**

Default value: **'score'**

'apply_rating_threshold': This parameter determines if the `RatingThreshold` will be applied or not. If **'apply_rating_threshold'** is set to **'true'**, the rating threshold given in `RatingThreshold` will be applied.

List of values: **'true'**, **'false'**

Default value: **'true'**

'use_color_info': See `set_sample_identifier_param` for a description of this parameter.

List of values: **'true'**, **'false'**

Default value: As long as **'use_color_info'** has not been set, the value set with **'add_color_info'** in `create_sample_identifier` is used.

'use_texture_info': See `set_sample_identifier_param` for a description of this parameter.

List of values: **'true'**, **'false'**

Default value: As long as **'use_texture_info'** has not been set, the value set with **'add_texture_info'** in `create_sample_identifier` is used.

'image_resize_method': See `create_sample_identifier` for a description of this parameter.

List of values: **'none'**, **'scale_factor'**, **'subsampling_step'**, **'image_area'**

Default value: If the **'image_resize_method'** is not set explicitly by this operator, the value that has been set with `create_sample_identifier` or `set_sample_identifier_param` will be used.

'image_resize_value': See `create_sample_identifier` for a description of this parameter. Note the objects to be identified should appear approximately in the same scale in the sample images as well as in the query images.

Suggested values: 0.25, 0.5, 1.0, 2, 3, 4

Default value: If the **'image_resize_value'** is not set explicitly by this operator, the value that has been set with `create_sample_identifier` or `set_sample_identifier_param` will be used.

Parameters

- ▷ **Image** (input_object) (multichannel-)image $\leadsto$ object : byte
Image showing the object to be identified.
- ▷ **SampleIdentifier** (input_control) sample_identifier $\leadsto$ handle
Handle of the sample identifier.

- ▷ **NumResults** (input_control)integer $\leadsto$ integer
Number of suggested object indices.
Default: 1
Suggested values: NumResults $\in$ {1, 2, 3, 4, 5, 10}
- ▷ **RatingThreshold** (input_control)real $\leadsto$ real
Rating threshold.
Default: 0.0
Suggested values: RatingThreshold $\in$ {0.05, 0.1, 0.15, 0.2}
- ▷ **GenParamName** (input_control)attribute.name-array $\leadsto$ string
Generic parameter name.
Default: []
List of values: GenParamName $\in$ {'use_texture_info', 'use_color_info', 'image_resize_method', 'image_resize_value', 'rating_method', 'apply_rating_threshold'}
- ▷ **GenParamValue** (input_control)attribute.value-array $\leadsto$ real / string / integer
Generic parameter value.
Default: []
List of values: GenParamValue $\in$ {'true', 'false', 'distance', 'score', 'score_single'}
- ▷ **ObjectIdx** (output_control)integer(-array) $\leadsto$ integer
Index of the identified object.
- ▷ **Rating** (output_control)real(-array) $\leadsto$ real
Rating value of the identified object.

Result

If the parameters are valid, the operator `set_sample_identifier_param` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

clear_sample_identifier (: : SampleIdentifier :)

Free the memory of a sample identifier.

clear_sample_identifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

The operator `clear_sample_identifier` frees the memory of a sample identifier that was created by `create_sample_identifier`, `read_sample_identifier`, or

`deserialize_sample_identifier`. After calling `clear_sample_identifier`, the sample identifier can no longer be used. The handle `SampleIdentifier` becomes invalid.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

Parameters

- ▷ **SampleIdentifier** (input_control) sample_identifier ~ handle
Handle of the sample identifier.

Result

If the handle of the sample identifier is valid, the operator `clear_sample_identifier` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SampleIdentifier

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

<pre>create_sample_identifier (: : GenParamName, GenParamValue : SampleIdentifier)</pre>

Create a new sample identifier.

`create_sample_identifier` is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

The operator `create_sample_identifier` creates a new sample identifier. Alternatively, an already available sample identifier can be read from file with the operator `read_sample_identifier`.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

Note that if you want to use color information, you must specify this explicitly by setting the generic parameter `'add_color_info'` to `'true'`.

The generic parameters can be used to influence the behavior of the sample identifier. Typically, only `'add_color_info'` must be considered. The parameters and their corresponding values can be specified by using `GenParamName` and `GenParamValue`, respectively. The following values for `GenParamName` are possible:

'add_color_info': This parameter determines if color information is used for the identification. If **'add_color_info'** is set to **'true'**, color information is used. Note that in this case, all images used for the preparation and the training of the sample identifier must be RGB color images. If **'add_color_info'** is set to **'false'**, no color information is used. Use color information, if the objects to be identified have different colors and if the illumination can be controlled to some degree. In this case, the use of color information makes the identification more robust.

List of values: **'true'**, **'false'**

Default value: **'false'**

'add_texture_info': This parameter determines if texture information is used for the identification. If **'add_texture_info'** is set to **'true'**, texture information is used. If **'add_texture_info'** is set to **'false'**, no texture information is used. Typically, **'add_texture_info'** should be set to **'true'**, because sample-based identification requires textured objects. Note that at least one of the two generic parameters **'add_color_info'** and **'add_texture_info'** must be set to **'true'**.

List of values: **'true'**, **'false'**

Default value: **'true'**

'image_resize_method': To speed up the identification process, the images are resized internally to a given size or by a given factor. If **'none'** is selected, no resizing will be done. For **'scale_factor'**, a constant scale factor can be set and for **'subsampling_step'**, a constant subsampling step, i.e., the inverse of the scale factor can be set. Finally, for **'image_area'**, a constant size of the resized image can be specified. The corresponding values can be set with the **'image_resize_value'** (see below).

To make the identification process faster, choose parameters that lead to a smaller internal image, i.e., use smaller scale factors or image sizes or a larger subsampling step. If the objects to be identified show high-frequency texture, the identification result may become better, if a larger internal image size is used, because otherwise the texture may be eliminated in the resized images.

List of values: **'none'**, **'scale_factor'**, **'subsampling_step'**, **'image_area'**

Default value: **'image_area'**

'image_resize_value': With this parameter, the selected **'image_resize_method'** can be parameterized. If **'image_resize_method'** is set to **'scale_factor'**, the value of **'image_resize_value'** defines the scale factor to be used. If **'image_resize_method'** is set to **'subsampling_step'**, the value of **'image_resize_value'** defines the subsampling step, i.e., the inverse of the scale factor. If **'image_resize_method'** is set to **'image_area'**, the value of **'image_resize_value'** defines the area of the resized image given in megapixels, i.e., in million pixels.

Suggested values: 0.25, 0.5, 1.0, 2, 3, 4

Default value: The default value depends on the selected **'image_resize_method'**. It is

- 0.5 for **'scale_factor'**,
- 2.0 for **'subsampling_step'**, and
- 0.5 for **'image_area'**.

Parameters

- ▷ **GenParamName** (input_control) attribute.name-array $\leadsto$ *string*
Parameter name.
Default: []
List of values: GenParamName $\in$ {**'image_resize_method'**, **'image_resize_value'**, **'add_texture_info'**, **'add_color_info'**}
- ▷ **GenParamValue** (input_control) attribute.value-array $\leadsto$ *string / real / integer*
Parameter value.
Default: []
Suggested values: GenParamValue $\in$ {**'none'**, **'scale_factor'**, **'subsampling_step'**, **'image_area'**, 0.25, 0.5, 0.75, 1.0, 2, 3, 4, **'true'**, **'false'**}
- ▷ **SampleIdentifier** (output_control) sample_identifier $\leadsto$ *handle*
Handle of the sample identifier.

Result

If the parameters are valid, the operator **create_sample_identifier** returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

```
deserialize_sample_identifier (
    : : SerializedItemHandle : SampleIdentifier )
```

Deserialize a serialized sample identifier.

deserialize_sample_identifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

`deserialize_sample_identifier` deserializes a sample identifier that was serialized by `serialize_sample_identifier` (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The serialized sample identifier is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created sample identifier with the handle `SampleIdentifier`.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

Parameters

- ▷ **SerializedItemHandle** (input_control) `serialized_item` $\leadsto$ *handle*
Handle of the serialized item.
- ▷ **SampleIdentifier** (output_control) `sample_identifier` $\leadsto$ *handle*
Handle of the sample identifier.

Result

If the parameters are valid, the operator `deserialize_sample_identifier` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

get_sample_identifier_object_info (: : SampleIdentifier, ObjectIdx, InfoName : InfoValue)

Retrieve information about an object of a sample identifier.

get_sample_identifier_object_info is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

[get_sample_identifier_object_info](#) retrieves information from the [SampleIdentifier](#). This information comprises the number of objects and object samples as well as their indices. Furthermore, the information set with [set_sample_identifier_object_info](#) can be retrieved.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

The parameter [ObjectIdx](#) defines the index of the object for which information is retrieved. Note that this parameter is not evaluated if [InfoName](#) is set to 'num_preparation_objects', 'preparation_object_idx', 'num_training_objects', or 'training_object_idx'.

[InfoName](#) defines the kind of information to be returned in [InfoValue](#). The following values for [InfoName](#) are possible:

'num_preparation_objects': The number of preparation objects. Note that all preparation objects for which the object index has been set to 'unknown', are counted as one single preparation object.

'preparation_object_idx': The list of indices of all available preparation objects. Note that this list will contain the string 'unknown', if the object index of at least one preparation object has been set to 'unknown'.

'num_preparation_samples': The number of preparation samples for the preparation object indicated by [ObjectIdx](#).

'preparation_sample_idx': The list of indices of all available preparation samples for the preparation object indicated by [ObjectIdx](#).

'num_training_objects': The number of training objects.

'training_object_idx': The list of indices of all available training objects.

'num_training_samples': The number of training samples for the training object indicated by [ObjectIdx](#).

'training_sample_idx': The list of indices of all available training samples for the training object indicated by [ObjectIdx](#).

'preparation_object_name': The information of the preparation object that has been set with [set_sample_identifier_object_info](#) for the preparation object indicated by [ObjectIdx](#).

'training_object_name': The information of the training object that has been set with [set_sample_identifier_object_info](#) for the training object indicated by [ObjectIdx](#).

Parameters

- ▷ **SampleIdentifier** (input_control) sample_identifier $\leadsto$ handle
 Handle of the sample identifier.
- ▷ **ObjectIdx** (input_control) integer(-array) $\leadsto$ integer / string
 Index of the object for which information is retrieved.
Suggested values: ObjectIdx $\in$ {0, 1, 2, 3, 4, 5, 'unknown'}

- ▷ **InfoName** (input_control) attribute.name(-array) $\leadsto$ *string*
 Define, for which kind of object information is retrieved.
Default: 'num_training_objects'
List of values: InfoName $\in$ {'num_preparation_objects', 'preparation_object_idx',
 'num_preparation_samples', 'preparation_sample_idx', 'num_training_objects', 'training_object_idx',
 'num_training_samples', 'training_sample_idx', 'preparation_object_name', 'training_object_name'}
- ▷ **InfoValue** (output_control) attribute.value(-array) $\leadsto$ *integer / string*
 Information about the object.

Result

If the parameters are valid, the operator `get_sample_identifier_object_info` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_sample_identifier_param (: : SampleIdentifier, GenParamName : GenParamValue)
--

Get selected parameters of a sample identifier.

get_sample_identifier_param is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

The operator `get_sample_identifier_param` allows to query the values of the different parameters of the given `SampleIdentifier`.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

The values of the following parameters can be queried:

'add_color_info': Do the operators `add_sample_identifier_preparation_data` and `add_sample_identifier_training_data` add color information to the `SampleIdentifier`?

'add_texture_info': Do the operators `add_sample_identifier_preparation_data` and `add_sample_identifier_training_data` add texture information to the `SampleIdentifier`?

'use_color_info': Is the `SampleIdentifier` configured to use color information for the identification with `apply_sample_identifier`?

'use_texture_info': Is the `SampleIdentifier` configured to use texture information for the identification with `apply_sample_identifier`?

'image_resize_method': The selected image resize method.

'image_resize_value': The current image resize value.

'*rating_method*': The selected rating method which is used by [apply_sample_identifier](#).

Parameters

- ▷ **SampleIdentifier** (input_control) *sample_identifier* $\leadsto$ *handle*
Handle of the sample identifier.
- ▷ **GenParamName** (input_control) *attribute.name* $\leadsto$ *string*
Parameter name.
Default: 'rating_method'
List of values: `GenParamName` $\in$ {'add_texture_info', 'add_color_info', 'use_texture_info', 'use_color_info', 'image_resize_method', 'image_resize_value', 'rating_method'}
- ▷ **GenParamValue** (output_control) *attribute.value* $\leadsto$ *real* / *string* / *integer*
Parameter value.

Result

If the parameters are valid, the operator `get_sample_identifier_param` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
prepare_sample_identifier ( : : SampleIdentifier,  
                             RemovePreparationData, GenParamName, GenParamValue : )
```

Adapt the internal data structure of a sample identifier to the objects to be identified.

prepare_sample_identifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

`prepare_sample_identifier` prepares the given [SampleIdentifier](#) using the preparation data, which have been set with [add_sample_identifier_preparation_data](#).

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

In order to achieve the maximum identification rate, the internal data structure of the [SampleIdentifier](#) must be adapted to the kind of objects to be identified.

To prepare the [SampleIdentifier](#), first, all the relevant sample images of the objects to be identified must be added with [add_sample_identifier_preparation_data](#). Then, with the call of `prepare_sample_identifier`, the internal data structure of the [SampleIdentifier](#) is adapted to the features of the provided sample images.

This process needs a lot of resources. Both, memory consumption and runtime are fairly high. E.g., if 100 sample images are used to prepare the sample identifier, approximately 300 MB of memory are required and the runtime will be in the range of a few minutes. If 1000 sample images are used, expect a memory consumption of about 2 GB and a runtime in the range of an hour.

Especially the preparation data requires a lot of memory. Typically, this data is no longer needed after the preparation of the sample identifier. Therefore, it can be removed by setting the parameter `RemovePreparationData` to `'true'`.

As an alternative to the preparation, e.g., if you are not able to spend this much memory and/or time, and if you are fine with a slightly higher misidentification rate, you can just read a sample identifier that was previously prepared with samples of similar object kinds from file (see `read_sample_identifier`).

To reuse the preparation data for the training, you can derive training data from the preparation data. This saves the effort to add training data separately with `add_sample_identifier_training_data` (see `train_sample_identifier` for a description of the training of the sample identifier). Note that the training data require far less memory than the preparation data. If the generic parameter `'copy_preparation_data_to_training_data'` is set to `'true'` (which is the default), for all sample images that have been added with `add_sample_identifier_preparation_data` and for which the object index has been set, training data is automatically derived. The object index that has been set with `add_sample_identifier_preparation_data` is taken unchanged. But note that the object sample index may be changed, because it is renumbered consecutively, starting with zero.

Parameters

- ▷ **SampleIdentifier** (input_control) sample_identifier $\leadsto$ handle
Handle of the sample identifier.
- ▷ **RemovePreparationData** (input_control) string $\leadsto$ string
Indicates if the preparation data should be removed.
Default: `'true'`
List of values: `RemovePreparationData` $\in$ `{'true', 'false'}`
- ▷ **GenParamName** (input_control) attribute.name-array $\leadsto$ string
Generic parameter name.
Default: []
List of values: `GenParamName` $\in$ `{'copy_preparation_data_to_training_data'}`
- ▷ **GenParamValue** (input_control) attribute.value-array $\leadsto$ string / integer / real
Generic parameter value.
Default: []
List of values: `GenParamValue` $\in$ `{'true', 'false'}`

Result

If the parameters are valid, the operator `prepare_sample_identifier` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

read_sample_identifier (: : FileName : SampleIdentifier)

Read a sample identifier from a file.

read_sample_identifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

The operator `read_sample_identifier` reads a sample identifier, which has been written with `write_sample_identifier`, from the file `FileName`. The default HALCON file extension for the sample identifier is 'sid'.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ *string*
File name.
File extension: .sid
- ▷ **SampleIdentifier** (output_control) sample_identifier $\leadsto$ *handle*
Handle of the sample identifier.

Result

If the file name is valid, the operator `read_sample_identifier` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

```
remove_sample_identifier_preparation_data (
    : : SampleIdentifier, ObjectIdx, ObjectSampleIdx : )
```

Remove preparation data from a sample identifier.

remove_sample_identifier_preparation_data is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

`remove_sample_identifier_preparation_data` removes preparation data from a sample identifier.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

`ObjectIdx` defines the index of the preparation object, of which samples should be removed. To remove preparation samples of preparation objects for which the object index has been set to 'unknown' with `add_sample_identifier_preparation_data`, set `ObjectIdx` to 'unknown'. The indices of all currently available preparation objects can be queried using `get_sample_identifier_object_info`.

`ObjectSampleIdx` defines the index of the preparation sample that should be removed. Removing the last preparation sample of a preparation object will remove also the corresponding preparation object itself from the `SampleIdentifier`. To remove all preparation samples of the preparation object defined by `ObjectIdx`, `ObjectSampleIdx` can be set to 'all'.

To remove all preparation samples of **all** preparation objects from the `SampleIdentifier`, set both `ObjectIdx` and `ObjectSampleIdx` to 'all'.

Parameters

- ▷ **SampleIdentifier** (input_control) sample_identifier $\leadsto$ handle
Handle of the sample identifier.
- ▷ **ObjectIdx** (input_control) integer $\leadsto$ integer / string
Index of the preparation object, of which samples should be removed.
Suggested values: ObjectIdx $\in$ {0, 1, 2, 3, 4, 5, 'all', 'unknown'}
- ▷ **ObjectSampleIdx** (input_control) integer $\leadsto$ integer / string
Index of the preparation sample that should be removed.
Suggested values: ObjectSampleIdx $\in$ {0, 1, 2, 3, 4, 5, 'all'}

Result

If the parameters are valid, the operator `remove_sample_identifier_preparation_data` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
remove_sample_identifier_training_data ( : : SampleIdentifier,
      ObjectIdx, ObjectSampleIdx : )
```

Remove training data from a sample identifier.

remove_sample_identifier_training_data is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

`remove_sample_identifier_training_data` removes training data from a sample identifier.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

[ObjectIdx](#) defines the index of the training object, of which samples should be removed.

[ObjectSampleIdx](#) defines the index of the training sample that should be removed. To remove all training samples of the training object defined by [ObjectIdx](#), [ObjectSampleIdx](#) can be set to 'all'. This will remove also the corresponding training object itself from the [SampleIdentifier](#).

To remove all training samples of all training objects from the [SampleIdentifier](#), set both [ObjectIdx](#) and [ObjectSampleIdx](#) to 'all'.

Parameters

- ▷ **SampleIdentifier** (input_control) sample_identifier $\leadsto$ handle
Handle of the sample identifier.
- ▷ **ObjectIdx** (input_control) integer $\leadsto$ integer / string
Index of the training object, from which samples should be removed.
Suggested values: ObjectIdx $\in$ {0, 1, 2, 3, 4, 5, 'all'}
- ▷ **ObjectSampleIdx** (input_control) integer $\leadsto$ integer / string
Index of the training sample that should be removed.
Suggested values: ObjectSampleIdx $\in$ {0, 1, 2, 3, 4, 5, 'all'}

Result

If the parameters are valid, the operator `remove_sample_identifier_training_data` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

[set_sample_identifier_object_info](#)

Module

Matching

```
serialize_sample_identifier (
    : : SampleIdentifier : SerializedItemHandle )
```

Serialize a sample identifier.

serialize_sample_identifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

`serialize_sample_identifier` serializes the data of a sample identifier (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The same data that is written in a file by `write_sample_identifier` is converted to a serialized item. The sample identifier is defined by the handle `SampleIdentifier`. The serialized sample identifier is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_sample_identifier`.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

Parameters

- ▷ **SampleIdentifier** (input_control) sample_identifier ~ handle
Handle of the sample identifier.
- ▷ **SerializedItemHandle** (output_control) serialized_item ~ handle
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_sample_identifier` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`prepare_sample_identifier`, `train_sample_identifier`,

Possible Successors

`clear_sample_identifier`

Alternatives

`write_sample_identifier`

Module

Matching

```
set_sample_identifier_object_info ( : : SampleIdentifier,
    ObjectIdx, InfoName, InfoValue : )
```

Define a name or a description for an object of a sample identifier.

set_sample_identifier_object_info is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

`set_sample_identifier_object_info` sets information like a name or a description for an object of the `SampleIdentifier`. This information can then be retrieved with `get_sample_identifier_object_info`.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

To set information for preparation objects, set `InfoName` to `'preparation_object_name'`. To set information for training objects, set `InfoName` to `'training_object_name'`. The information itself is set with the parameter `InfoValue`.

Parameters

- ▷ **SampleIdentifier** (input_control) sample_identifier $\leadsto$ handle
Handle of the sample identifier.
- ▷ **ObjectIdx** (input_control) integer(-array) $\leadsto$ integer / string
Index of the object for which information is set.
Suggested values: ObjectIdx $\in$ {0, 1, 2, 3, 4, 5}
- ▷ **InfoName** (input_control) attribute.name $\leadsto$ string
Define, for which kind of object information is set.
Default: 'training_object_name'
List of values: InfoName $\in$ {'preparation_object_name', 'training_object_name'}
- ▷ **InfoValue** (input_control) attribute.value(-array) $\leadsto$ string
Information about the object.

Result

If the parameters are valid, the operator `set_sample_identifier_object_info` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

```
set_sample_identifier_param ( : : SampleIdentifier, GenParamName,
                               GenParamValue : )
```

Set selected parameters of a sample identifier.

set_sample_identifier_param is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

The operator `set_sample_identifier_param` is used to set or change the different parameters of the given `SampleIdentifier`.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

The following parameters can be used to influence the behavior of the `SampleIdentifier`. These parameters and their corresponding values can be specified by using `GenParamName` and `GenParamValue`, respectively. The following values for `GenParamName` are possible:

'use_color_info': This parameter determines if color information is used for the identification. If **'use_color_info'** is set to **'true'**, color information is used. Note that in this case, the images used for **apply_sample_identifier** must be RGB color images. If **'use_color_info'** is set to **'false'**, no color information is used. Use color information if the objects to be identified have different colors and the illumination can be controlled to some degree. In this case, the use of color information makes the identification more robust.

Note that in contrast to the generic parameter **'add_color_info'**, which can only be set in **create_sample_identifier**, this parameter affects only the operator **apply_sample_identifier**. With this, it is, e.g., possible to train the sample identifier using texture and color and to identify selected objects only based on the texture information.

List of values: **'true'**, **'false'**

Default value: As long as **'use_color_info'** has not been set, the value set with **'add_color_info'** in **create_sample_identifier** is used.

'use_texture_info': This parameter determines if texture information is used for the identification. If **'use_texture_info'** is set to **'true'**, texture information is used. If **'use_texture_info'** is set to **'false'**, no texture information is used. Typically, **'use_texture_info'** should be set to **'true'**, because sample-based identification requires textured objects. Note that at least one of the two generic parameters **'use_color_info'** and **'use_texture_info'** must be set to **'true'**.

Note that in contrast to the generic parameter **'add_texture_info'**, which can only be set in **create_sample_identifier**, this parameter affects only the operator **apply_sample_identifier**.

List of values: **'true'**, **'false'**

Default value: As long as **'use_texture_info'** has not been set, the value set with **'add_texture_info'** in **create_sample_identifier** is used.

'image_resize_method': See **create_sample_identifier** for a description of this parameter.

List of values: **'none'**, **'scale_factor'**, **'subsampling_step'**, **'image_area'**

Default value: If the **'image_resize_method'** is not set explicitly by this operator, the value that has been set with **create_sample_identifier** will be used.

'image_resize_value': See **create_sample_identifier** for a description of this parameter.

Suggested values: 0.25, 0.5, 1.0, 2, 3, 4

Default value: If the **'image_resize_value'** is not set explicitly by this operator, the value that has been set with **create_sample_identifier** will be used.

'rating_method': See **apply_sample_identifier** for a description of this parameter that is used only by **apply_sample_identifier**.

List of values: **'distance'**, **'score'**, **'score_single'**

Default value: **'score'**

Parameters

- ▷ **SampleIdentifier** (input_control) sample_identifier $\leadsto$ handle
Handle of the sample identifier.
- ▷ **GenParamName** (input_control) attribute.name $\leadsto$ string
Parameter name.
Default: **'rating_method'**
List of values: GenParamName $\in$ {**'use_texture_info'**, **'use_color_info'**, **'image_resize_method'**, **'image_resize_value'**, **'rating_method'**}
- ▷ **GenParamValue** (input_control) attribute.value $\leadsto$ real / integer / string
Parameter value.
Default: **'score_single'**
List of values: GenParamValue $\in$ {**'true'**, **'false'**, **'none'**, **'scale_factor'**, **'subsampling_step'**, **'distance'**, **'score'**, **'score_single'**, **'image_area'**, 0.25, 0.5, 0.75, 1.0, 2, 3, 4}

Result

If the parameters are valid, the operator **set_sample_identifier_param** returns the value 2 (**H_MSG_TRUE**). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
train_sample_identifier ( : : SampleIdentifier, GenParamName,
                          GenParamValue : )
```

Train a sample identifier.

`train_sample_identifier` is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

`train_sample_identifier` trains the given [SampleIdentifier](#) using the training data, which has been set with `add_sample_identifier_training_data`.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

In order to be able to identify objects, the [SampleIdentifier](#) must be trained with a representative set of sample images of the objects to be identified (see `add_sample_identifier_training_data`).

To train the [SampleIdentifier](#), first, all the relevant sample images of the objects to be identified must be added with `add_sample_identifier_training_data`. Alternatively, the preparation data can be reused. See `prepare_sample_identifier` for an explanation on how to reuse preparation data for the training of the sample identifier. Then, with the call of `train_sample_identifier`, the [SampleIdentifier](#) is trained.

Note that the training itself is very fast and does not consume a lot of memory. Therefore, it is very easy to retrain the [SampleIdentifier](#), e.g., after new objects were added or already trained objects were removed from the [SampleIdentifier](#).

To retrain an existing sample identifier with new objects, just add the relevant sample images with `add_sample_identifier_training_data` and call `train_sample_identifier`, again. To remove objects, use the operator `remove_sample_identifier_training_data` and retrain the sample identifier with `train_sample_identifier`.

Note that the training of the sample identifier is only possible, if the sample identifier contains training data for at least two different training objects.

The generic parameters [GenParamName](#) and [GenParamValue](#) are intended for future use, only.

Parameters

- ▷ **`SampleIdentifier`** (input_control) `sample_identifier` ~ handle
 Handle of the sample identifier.

▷ **GenParamName** (input_control) attribute.name-array $\leadsto$ string
Parameter name.
Default: []
List of values: GenParamName $\in$ {}

▷ **GenParamValue** (input_control) attribute.value-array $\leadsto$ real / string / integer
Parameter value.
Default: []
List of values: GenParamValue $\in$ {}

Result

If the parameters are valid, the operator `train_sample_identifier` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

write_sample_identifier (: : SampleIdentifier, FileName :)

Write a sample identifier to a file.

write_sample_identifier is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators for Deep-Learning-based classification instead, for details see [Deep Learning / Classification](#).

The operator `write_sample_identifier` writes a sample identifier to the file `FileName`. The sample identifier can be read again with `read_sample_identifier`. The default HALCON file extension for the sample identifier is 'sid'.

For an explanation of the concept of sample-based identification see the introduction of chapter [Legacy / Identification](#).

Parameters

▷ **SampleIdentifier** (input_control) sample_identifier $\leadsto$ handle
Handle of the sample identifier.

▷ **FileName** (input_control) filename.write $\leadsto$ string
File name.
File extension: .sid

Result

If the file name is valid (write permission), the operator `write_sample_identifier` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

adapt_template (Image : : TemplateID :)
--

Adapting a template to the size of an image.

adapt_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `adapt_template` serves to adapt a template which has been created by `create_template` to the size of an image. The operator `adapt_template` can be called before the template is used with images of another size, or if the image used to create the template had another size. If it is not called explicitly it will be called internally each time another image size is used. The contents of the image is hereby irrelevant; only the width of `Image` will be considered.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte
Image which determines the size of the later matching.
- ▷ **TemplateID** (input_control) template $\leadsto$ *handle*
Template number.

Result

If the parameter values are correct, the operator `adapt_template` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `TemplateID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_template`, `create_template_rot`, `read_template`

Possible Successors

`set_reference_template`, `best_match`, `fast_match`, `fast_match_mg`,
`set_offset_template`, `best_match_mg`, `best_match_pre_mg`, `best_match_rot`,
`best_match_rot_mg`

Module

Matching

```
best_match ( Image : : TemplateID, MaxError, SubPixel : Row,
             Column, Error )
```

Searching the best matching of a template and an image.

`best_match` is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `best_match` performs a matching of the template of `TemplateID` and `Image`. Hereby the template will be moved over the points of `Image` so that the template will lie always inside `Image`. `best_match` works similar to `fast_match`, with the exception, that each time a better match is found the value of `MaxError` is internally updated to a lower value to reduce runtime.

With regard to the parameter `SubPixel`, the position will be indicated by subpixel accuracy. The matching criterion (“displaced frame difference”) is defined as follows:

$$error[row, col] = \frac{\sum_{u,v} |\text{Image}[row - u, col - v] - \text{TemplateID}[u, v]|}{area(\text{TemplateID})}$$

The runtime of the operator depends on the size of the domain of `Image`. Therefore it is important to restrict the domain as far as possible, i.e. to apply the operator only in a very confined “region of interest”. The parameter `MaxError` determines the maximal error which the searched position is allowed to have at most. The lower this value is, the faster the operator runs.

`Row` and `Column` return the position of the best match, whereby `Error` indicates the average difference of the gray values. If no position with an error below `MaxError` was found the position (0, 0) and a matching result of 255 for `Error` are returned. In this case `MaxError` has to be set larger.

The maximum error of the position (without noise) is 0.1 pixel. The average error is 0.03 pixel.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ object : byte
Input image inside of which the pattern has to be found.
- ▷ **TemplateID** (input_control) template $\leadsto$ handle
Template number.
- ▷ **MaxError** (input_control) real $\leadsto$ real
Maximum average difference of the gray values.
Default: 20.0
Suggested values: `MaxError` $\in$ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0}
Value range: $0 \leq \text{MaxError} \leq 255$
Minimum increment: 1
Recommended increment: 3
- ▷ **SubPixel** (input_control) string $\leadsto$ string
Subpixel accuracy in case of 'true'.
Default: 'false'
List of values: `SubPixel` $\in$ {'true', 'false'}

- ▷ **Row** (output_control) point.y(-array) $\leadsto$ *real*
Row position of the best match.
- ▷ **Column** (output_control) point.x(-array) $\leadsto$ *real*
Column position of the best match.
- ▷ **Error** (output_control) real(-array) $\leadsto$ *real*
Average divergence of the gray values of the best match.

Result

If the parameter values are correct, the operator `best_match` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`create_template`, `read_template`, `set_offset_template`, `set_reference_template`, `adapt_template`, `draw_region`, `draw_rectangle1`, `reduce_domain`

Alternatives

`fast_match`, `fast_match_mg`, `best_match_mg`, `best_match_pre_mg`, `best_match_rot`, `best_match_rot_mg`, `exhaustive_match`, `exhaustive_match_mg`

Module

Matching

```
best_match_mg ( Image : : TemplateID, MaxError, SubPixel,
                NumLevels, WhichLevels : Row, Column, Error )
```

Searching the best gray value matches in a pyramid.

`best_match_mg` is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

`best_match_mg` applies gray value matching using an image pyramid. `best_match_mg` works analogously to `best_match`, but it is faster due to the use of a pyramid. Input is an image with an optionally reduced domain. The template is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image. The parameter `MaxError` specifies the maximum error for template matching. Using smaller values results in a reduced runtime but it is possible that the pattern might be missed. The value of `MaxError` has to be chosen larger compared with `best_match`, because the error at higher levels of the pyramid is often larger.

`SubPixel` specifies if the result is calculated with sub pixel accuracy or not. A value of 1 for `NumLevels` results in an operator similar to `best_match`, i.e. only the original gray values are used. For values larger than 1, the algorithm starts at the lowest resolution and searches for a position with the lowest matching error. At the next higher resolution this position is refined. This is continued up to the maximum resolution (`WhichLevels = 'all'`). As an alternative Method the mode `WhichLevels` with value `'original'` can be used. In this case not only the position with the lowest error but all points below `MaxError` are analyzed further on in the next higher resolution. This method is slower but it is more stable and the possibility to miss the correct position is very low. In this case it is often possible to start with a lower resolution (higher level in Pyramid, i.e. larger value for `NumLevels`) which leads to a reduced runtime. Besides the values `'all'` and `'original'` for `WhichLevels` you can specify the pyramid level explicitly where to switch between a “match all” and the “best match”. Here 0 corresponds to `'original'` and `NumLevels - 1` is equivalent to `'all'`. A value in-between is in most cases a good compromise between speed and a stable detection. A larger value for `WhichLevels` results in a reduced runtime, a smaller value results in a more stable detection. The value of `NumLevels` has to be equal or smaller than the value used to create the template.

The position of the found matching position is returned in `Row` and `Column`. The corresponding error is given in `Error`. If no point below `MaxError` is found a value of 255 for `Error` and 0 for `Row` and `Column` is

returned. If the desired object is missed (no object found or wrong position) you have to set `MaxError` higher or `WhichLevels` lower. Check also if the illumination has changed (see `set_offset_template`).

The maximum error of the position (without noise) is 0.1 pixel. The average error is 0.03 pixel.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ object : byte
Input image inside of which the pattern has to be found.
- ▷ **TemplateID** (input_control) template $\leadsto$ handle
Template number.
- ▷ **MaxError** (input_control) real $\leadsto$ real
Maximal average difference of the gray values.
Default: 30.0
Suggested values: `MaxError` $\in$ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0}
Value range: $0 \leq \text{MaxError} \leq 255$
Minimum increment: 1
Recommended increment: 3
- ▷ **SubPixel** (input_control) string $\leadsto$ string
Exactness in subpixels in case of 'true'.
Default: 'false'
List of values: `SubPixel` $\in$ {'true', 'false'}
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer
Number of the used resolution levels.
Default: 4
Suggested values: `NumLevels` $\in$ {1, 2, 3, 4, 5, 6}
- ▷ **WhichLevels** (input_control) integer $\leadsto$ integer / string
Resolution level up to which the method "best match" is used.
Default: 2
Suggested values: `WhichLevels` $\in$ {'all', 'original', 0, 1, 2, 3, 4, 5, 6}
- ▷ **Row** (output_control) point.y $\leadsto$ real
Row position of the best match.
- ▷ **Column** (output_control) point.x $\leadsto$ real
Column position of the best match.
- ▷ **Error** (output_control) real $\leadsto$ real
Average divergence of the gray values in the best match.

Result

If the parameter values are correct, the operator `best_match_mg` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`create_template`, `read_template`, `adapt_template`, `draw_region`, `draw_rectangle1`, `reduce_domain`, `set_reference_template`, `set_offset_template`

Alternatives

`fast_match`, `fast_match_mg`, `best_match`, `best_match_pre_mg`, `best_match_rot`, `best_match_rot_mg`, `exhaustive_match`, `exhaustive_match_mg`

Module

Matching

```
best_match_pre_mg ( ImagePyramid : : TemplateID, MaxError,
                    SubPixel, NumLevels, WhichLevels : Row, Column, Error )
```

Searching the best gray value matches in a pre generated pyramid.

best_match_pre_mg is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

best_match_pre_mg applies gray value matching using an image pyramid. **best_match_pre_mg** works analogously to **best_match_mg**, but it makes use of pre calculated pyramid which has to be generated beforehand using **gen_gauss_pyramid**. This reduces runtime if more than one match has to be done or the pyramid has been used otherwise. The pyramid has to be generated using the zooming factor 0.5 and the mode 'constant'.

Parameters

- ▷ **ImagePyramid** (input_object)singlechannelimage-array $\leadsto$ object : byte
Image pyramid inside of which the pattern has to be found.
- ▷ **TemplateID** (input_control) template $\leadsto$ handle
Template number.
- ▷ **MaxError** (input_control) real $\leadsto$ real
Maximal average difference of the gray values.
Default: 30.0
Suggested values: MaxError $\in$ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0}
Value range: $0 \leq \text{MaxError} \leq 255$
Minimum increment: 1
Recommended increment: 3
- ▷ **SubPixel** (input_control)string $\leadsto$ string
Exactness in subpixels in case of 'true'.
Default: 'false'
List of values: SubPixel $\in$ {'true', 'false'}
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer
Number of the used resolution levels.
Default: 3
Suggested values: NumLevels $\in$ {1, 2, 3, 4, 5, 6}
- ▷ **WhichLevels** (input_control)integer $\leadsto$ integer / string
Resolution level up to which the method "best match" is used.
Default: 'original'
Suggested values: WhichLevels $\in$ {'all', 'original', 0, 1, 2, 3, 4, 5, 6}
- ▷ **Row** (output_control) point.y $\leadsto$ real
Row position of the best match.
- ▷ **Column** (output_control) point.x $\leadsto$ real
Column position of the best match.
- ▷ **Error** (output_control) real $\leadsto$ real
Average divergence of the gray values in the best match.

Result

If the parameter values are correct, the operator **best_match_pre_mg** returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via **set_system** ('no_object_result', <Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

gen_gauss_pyramid, **create_template**, **read_template**, **adapt_template**, **draw_region**, **draw_rectangle1**, **reduce_domain**, **set_reference_template**

Alternatives

[fast_match](#), [fast_match_mg](#), [exhaustive_match](#), [exhaustive_match_mg](#)

Module

Matching

```
best_match_rot ( Image : : TemplateID, AngleStart, AngleExtend,
                 MaxError, SubPixel : Row, Column, Angle, Error )
```

Searching the best matching of a template and an image with rotation.

best_match_rot is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `best_match_rot` performs a matching of the template of [TemplateID](#) and [Image](#). It works similar to [best_match](#) with the extension that the pattern can be rotated. The parameters [AngleStart](#) and [AngleExtend](#) define the maximum rotation of the pattern: [AngleStart](#) specifies the maximum counter clock-wise rotation and [AngleExtend](#) the maximum clockwise rotation relative to this angle. Both values have to be smaller or equal to the values used for the creation of the pattern (see [create_template_rot](#)). In addition to [best_match](#) `best_match_rot` returns the rotation angle of the pattern in [Angle](#) (radian). The accuracy of this angle depends on the parameter [AngleStep](#) of [create_template_rot](#). In the case of [SubPixel](#) = 'true' the position and the angle are calculated with "sub pixel" accuracy.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte
Input image inside of which the pattern has to be found.
- ▷ **TemplateID** (input_control) template $\leadsto$ *handle*
Template number.
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ *real*
Smallest Rotation of the pattern.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtend** (input_control) angle.rad $\leadsto$ *real*
Maximum positive Extension of [AngleStart](#).
Default: 0.79
Suggested values: AngleExtend $\in$ {6.28, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtend > 0
- ▷ **MaxError** (input_control) real $\leadsto$ *real*
Maximum average difference of the gray values.
Default: 30.0
Suggested values: MaxError $\in$ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0}
Value range: $0 \leq \text{MaxError} \leq 255$
Minimum increment: 1
Recommended increment: 3
- ▷ **SubPixel** (input_control) string $\leadsto$ *string*
Subpixel accuracy in case of 'true'.
Default: 'false'
List of values: SubPixel $\in$ {'true', 'false'}
- ▷ **Row** (output_control) point.y(-array) $\leadsto$ *real*
Row position of the best match.
- ▷ **Column** (output_control) point.x(-array) $\leadsto$ *real*
Column position of the best match.
- ▷ **Angle** (output_control) angle.rad(-array) $\leadsto$ *real*
Rotation angle of pattern.
- ▷ **Error** (output_control) real(-array) $\leadsto$ *real*
Average divergence of the gray values of the best match.

Result

If the parameter values are correct, the operator `best_match_rot` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`create_template_rot`, `read_template`, `set_offset_template`, `set_reference_template`, `adapt_template`, `draw_region`, `draw_rectangle1`, `reduce_domain`

Matching

best_match_rot_mg (Image : : TemplateID, AngleStart, AngleExtend, MaxError, SubPixel, NumLevels : Row, Column, Angle, Error)
--

Searching the best matching of a template and a pyramid with rotation.

best_match_rot_mg is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `best_match_rot_mg` performs a matching of the template of `TemplateID` and `Image`. It works similar to `best_match_mg` with the extension that the pattern can be rotated analogously to `best_match_rot`. The parameters `AngleStart` and `AngleExtend` define the maximum rotation of the pattern: `AngleStart` specifies the maximum counter clockwise rotation and `AngleExtend` the maximum clockwise rotation relative to this angle. Both values have to be smaller or equal to the values used for the creation of the pattern (see `create_template_rot`). In addition to `best_match_mg` `best_match_rot_mg` returns the rotation angle of the pattern in `Angle` (radian).

The value of `MaxError` must be set larger in comparison with the operator `best_match_rot`, because often the error is larger at higher levels of the pyramid.

In the case of `SubPixel = 'true'` the position and the angle are calculated with “sub pixel” accuracy.

The value of `NumLevels` has to be equal or smaller than the value used to create the template.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte
Input image inside of which the pattern has to be found.
- ▷ **TemplateID** (input_control) template $\leadsto$ *handle*
Template number.
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ *real*
Smallest Rotation of the pattern.
Default: -0.39
Suggested values: `AngleStart` $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtend** (input_control) angle.rad $\leadsto$ *real*
Maximum positive Extension of `AngleStart`.
Default: 0.79
Suggested values: `AngleExtend` $\in$ {6.28, 3.14, 1.57, 0.79, 0.39}
Restriction: `AngleExtend` > 0

- ▷ **MaxError** (input_control) real $\leadsto$ real
Maximum average difference of the gray values.
Default: 40.0
Suggested values: MaxError $\in \{0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0\}$
Value range: $0 \leq \text{MaxError} \leq 255$
Minimum increment: 1
Recommended increment: 1
- ▷ **SubPixel** (input_control) string $\leadsto$ string
Subpixel accuracy in case of 'true'.
Default: 'false'
List of values: SubPixel $\in \{'true', 'false'\}$
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer
Number of the used resolution levels.
Default: 3
Suggested values: NumLevels $\in \{1, 2, 3, 4, 5, 6\}$
- ▷ **Row** (output_control) point.y(-array) $\leadsto$ real
Row position of the best match.
- ▷ **Column** (output_control) point.x(-array) $\leadsto$ real
Column position of the best match.
- ▷ **Angle** (output_control) angle.rad(-array) $\leadsto$ real
Rotation angle of pattern.
- ▷ **Error** (output_control) real(-array) $\leadsto$ real
Average divergence of the gray values of the best match.

Result

If the parameter values are correct, the operator `best_match_rot_mg` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Matching

clear_template (: : TemplateID :)

Deallocation of the memory of a template.

clear_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `clear_template` deallocates the memory of a template which has been created by `create_template` or `create_template_rot`. After execution of the operator `clear_template` the template can no longer be used. The value of `TemplateID` is not valid. However, the number can be used again by further calls of `create_template` or `create_template_rot`.

Parameters

▷ **TemplateID** (input_control) template ~ handle
Template number.

Result

If the number of the template is valid, the operator `clear_template` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TemplateID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_template`, `create_template_rot`, `read_template`, `write_template`

Module

Matching

```
create_template ( Template : : FirstError, NumLevel, Optimize,
                  GrayValues : TemplateID )
```

Preparing a pattern for template matching.

`create_template` is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `create_template` preprocesses a pattern (`Template`), which is passed as an image, for the template matching. After the transformation, a number (`TemplateID`) is assigned to the template for being used in the further process. The shape and the size of `Template` can be chosen arbitrarily. You have to be aware, that the matching is only applied to that part of an image where `Template` fits completely into the image.

The template has been chosen such that it contains no pixels of the (changing) background. Here you can make use of the arbitrary shape of a template which is not restricted to a rectangle. To create a template region you can use segmentation operators like `threshold` or one of the `draw_*` operators. In the case of sub pixel accurate matching `Template` has in addition to be one pixel smaller than the pattern (i.e. one pixel border to the changing background). This can be done e.g., by applying the operator `erosion_circle`.

The parameter `NumLevel` specifies the number of pyramid levels (`NumLevel = 1` means only original gray values) which can be used for matching. The number of levels used later for matching will be below or equal this value. If the pattern becomes too small due to zooming, the maximum number of pyramid levels is automatically reduced (without error message).

The parameter `GrayValues` defines, whether the original gray values ('original', 'normalized') or the edge amplitude ('gradient', 'sobel') is used. With 'original' the sum of the differences is used as feature which is very stable and fast if there is no change in illumination. 'normalized' is used if the illumination changes. The method is a bit slower and not quite as stable. Note that 'normalized' allows to compensate additive illumination changes. If also multiplicative variations of the gray values occur, correlation-based matching should be used (`create_ncc_model`). If there is no change in illumination the mode 'original' should be used. The edge amplitude is another method to be invariant to changes in illumination. The disadvantage is the increased execution time and the higher sensitivity to changes in the shape of the pattern. The mode 'gradient' is slightly faster but more sensitive to noise.

The maximum error for matching has typically to be chosen higher when using the edge amplitude. The mode chosen by `GrayValues` leads automatically to calling the appropriate filter during the matching, if necessary.

As an alternative to the gradient approach the operator `set_offset_template` can be used, if the change in illumination is known.

The parameter `Optimize` specifies if the pattern has to be optimized for runtime. This optimization results in a longer time to create the template but reduces the time for matching. In addition the optimization leads to a more stable matching, i.e., the possibility to miss good matches is reduced. The optimization process selects the most stable and significant gray values to be tested first during the matching process. Using this technique a wrong match can be eliminated very early.

The reference position for the template is its center of gravity. I.e. if you apply the template to the original image the center of gravity is returned. This default reference can be adapted using the operator `set_reference_template`.

In sub pixel mode a special position correction is calculated which is added after each matching: The template is applied to the original image and the difference between the found position and the center of gravity is used as a correction vector. This is important for patterns in a textured context or for asymmetric pattern. For most templates this correction vector is near null.

Before the use of the template, which is stored independently of the image size, it can be adapted explicitly to the size of a definite image size by using `adapt_template`.

Parameters

- ▷ **Template** (input_object)singlechannelimage $\leadsto$ object : byte
Input image whose domain will be processed for the pattern matching.
- ▷ **FirstError** (input_control)integer $\leadsto$ integer
Not yet in use.
Default: 255
List of values: FirstError $\in$ {255}
- ▷ **NumLevel** (input_control)integer $\leadsto$ integer
Maximal number of pyramid levels.
Default: 4
List of values: NumLevel $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **Optimize** (input_control)string $\leadsto$ string
Kind of optimizing.
Default: 'sort'
List of values: Optimize $\in$ {'none', 'sort'}
- ▷ **GrayValues** (input_control)string $\leadsto$ string
Kind of gray values.
Default: 'original'
List of values: GrayValues $\in$ {'original', 'normalized', 'gradient', 'sobel'}
- ▷ **TemplateID** (output_control) template $\leadsto$ handle
Template number.

Result

If the parameters are valid, the operator `create_template` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

```
create_template_rot ( Template : : NumLevel, AngleStart,
                     AngleExtend, AngleStep, Optimize, GrayValues : TemplateID )
```

Preparing a pattern for template matching with rotation.

`create_template_rot` is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `create_template_rot` preprocesses a pattern, which is passed as an image, for the template matching. An extension to `create_template` the matching can be applied to rotated patterns. The parameters `AngleStart` and `AngleExtend` define the maximum rotation of the pattern: `AngleStart` specifies the maximum counter clockwise rotation and `AngleExtend` the maximum clockwise rotation relative to this angle. Therefore `AngleExtend` has to be smaller than 2π . With the parameter `AngleStep` the maximum angle resolution (on the highest resolution level) can be specified.

You have to be aware, that all possible rotations are calculated beforehand to reduce runtime during matching. This leads to a higher execution time for `create_template_rot` and high memory requirements for the template. The amount of memory depends on the parameters `AngleExtend` and `AngleStep`. The number of pyramid levels can be neglected. If A is the number of pixels of `Template`, the memory M needed for the template in byte is about:

$$M = \frac{A * 12 * \text{AngleExtend}}{\text{AngleStep}}$$

After the transformation, a number (`TemplateID`) is assigned to the template for being used in the further process.

A description of the other parameters can be found at the operator `create_template`.

Attention

You have to be aware, that depending on the resolution a large number of pre calculated patterns have to be created which might result in a large amount of memory needed.

Parameters

- ▷ **Template** (input_object)singlechannelimage $\rightsquigarrow$ object : byte
Input image whose domain will be processed for the pattern matching.
- ▷ **NumLevel** (input_control)integer $\rightsquigarrow$ integer
Maximal number of pyramid levels.
Default: 4
List of values: NumLevel $\in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$
- ▷ **AngleStart** (input_control)angle.rad $\rightsquigarrow$ real
Smallest Rotation of the pattern.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtend** (input_control) angle.rad $\rightsquigarrow$ real
Maximum positive Extension of `AngleStart`.
Default: 0.79
Suggested values: AngleExtend $\in \{6.28, 3.14, 1.57, 0.79, 0.39\}$
Restriction: AngleExtend > 0
- ▷ **AngleStep** (input_control) angle.rad $\rightsquigarrow$ real
Step rate (angle precision) of matching.
Default: 0.0982
Suggested values: AngleStep $\in \{0.3927, 0.1963, 0.0982, 0.0491, 0.0245\}$
Restriction: AngleStep > 0

- ▷ **Optimize** (input_control) string $\leadsto$ string
Kind of optimizing.
Default: 'sort'
List of values: Optimize $\in$ {'none', 'sort'}
- ▷ **GrayValues** (input_control) string $\leadsto$ string
Kind of gray values.
Default: 'original'
List of values: GrayValues $\in$ {'original', 'normalized', 'gradient', 'sobel'}
- ▷ **TemplateID** (output_control) template $\leadsto$ handle
Template number.

Result

If the parameters are valid, the operator `create_template_rot` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

deserialize_template (: : SerializedItemHandle : TemplateID)

Deserialize a serialized template.

deserialize_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

`deserialize_template` deserializes a template, that was serialized by `serialize_template` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized template is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created template with the handle `TemplateID`.

Parameters

- ▷ **SerializedItemHandle** (input_control) serialized_item $\leadsto$ handle
Handle of the serialized item.
- ▷ **TemplateID** (output_control) template $\leadsto$ handle
Template number.

Result

If the parameters are valid, the operator `deserialize_template` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

fast_match (`Image` : `Matches` : `TemplateID`, `MaxError` :)

Searching all good matches of a template and an image.

fast_match is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `fast_match` performs a matching of the template of `TemplateID` and `Image`. Hereby the template will be moved over the points of `Image` so that the template always lies completely inside of `Image`. The matching criterion (“displaced frame difference”) is defined as follows:

$$error[row, col] = \frac{\sum_{u,v} |Image[row - u, col - v] - TemplateID[u, v]|}{area(TemplateID)}$$

The difference between `fast_match` and `exhaustive_match` is that the matching for one position is stopped if the error is too high. This leads to a reduced runtime but one might miss correct matches. The runtime of the operator depends mainly on the size of the domain of `Image`. Therefore it is important to restrict the domain as far as possible, i.e. to apply the operator only in a very confined “region of interest”. The parameter `MaxError` determines the maximal error which the searched position is allowed to show. The lower this value is, the faster the operator runs.

All points which show a matching error smaller than `MaxError` will be returned in the output region `Matches`. This region can be used for further processing. For example by using a connection and `best_match` to find all the matching objects. If no point has a match error below `MaxError` the empty region (i.e no points) is returned.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte
Input image inside of which the pattern has to be found.
- ▷ **Matches** (output_object) region(-array) $\leadsto$ *object*
All points whose error lies below a certain threshold.
- ▷ **TemplateID** (input_control) template $\leadsto$ *handle*
Template number.
- ▷ **MaxError** (input_control) real $\leadsto$ *real*
Maximal average difference of the gray values.
Default: 20.0
Suggested values: `MaxError` $\in$ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0}
Value range: $0 \leq \text{MaxError} \leq 255$
Minimum increment: 1
Recommended increment: 1

Result

If the parameter values are correct, the operator `fast_match` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`create_template`, `read_template`, `adapt_template`, `draw_region`, `draw_rectangle1`, `reduce_domain`

Possible Successors

`connection`, `best_match`

Alternatives

`best_match`, `best_match_mg`, `fast_match_mg`, `exhaustive_match`, `exhaustive_match_mg`

Module

Matching

```
fast_match_mg ( Image : Matches : TemplateID, MaxError,
                NumLevel : )
```

Searching all good gray value matches in a pyramid.

fast_match_mg is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `fast_match_mg` like the operator `fast_match` performs a matching of the template of `TemplateID` and `Image`. In contrast to `fast_match`, however, the search for good matches starts in scaled down images (pyramid). The number of levels of the pyramid will be determined by `NumLevel`. Hereby the value 1 indicates that no pyramid will be used. In this case the operator `fast_match_mg` is equivalent to the operator `fast_match`. The value 2 triggers the search in the image with half the framesize. The search for all those points showing an error small enough in the scaled down image (error smaller than `MaxError`) will be refined at the corresponding positions in the original image (`Image`).

The runtime of matching depends on the parameter `MaxError`: the larger the value the longer is the processing time, because more points of the pattern have to be tested. If `MaxError` is too low the pattern will not be found. The value has therefore to be optimized for every application.

`NumLevel` indicates the number of levels of the pyramid, including the original image. Optionally a second value can be given. This value specifies the number (0..n) of the lowest level which is used for the matching. The region found up to this level will then be zoomed to the size of the original level. This can be used to increase the runtime in the case that the accuracy does not have to be so high.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ object : byte
Input image inside of which the pattern has to be found.
- ▷ **Matches** (output_object) region(-array) $\leadsto$ object
All points which have an error below a certain threshold.
- ▷ **TemplateID** (input_control) template $\leadsto$ handle
Template number.
- ▷ **MaxError** (input_control) real $\leadsto$ real
Maximal average difference of the gray values.
Default: 30.0
Suggested values: `MaxError` $\in$ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 17.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0}
Value range: $0 \leq \text{MaxError} \leq 255$
Minimum increment: 1
Recommended increment: 3
- ▷ **NumLevel** (input_control) integer(-array) $\leadsto$ integer
Number of levels in the pyramid.
Default: 3
Suggested values: `NumLevel` $\in$ {1, 2, 3, 4, 5, 6, 7, 8}

Result

If the parameter values are correct, the operator `fast_match_mg` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Matching

read_template (: : FileName : TemplateID)
--

Reading a template from file.

read_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `read_template` reads a matching template from file which has been written with `write_template`. The default HALCON file extension for a template is 'gvt'.

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ string
file name.
File extension: .gvt
- ▷ **TemplateID** (output_control) template $\leadsto$ handle
Template number.

Result

If the file name is valid, the operator `read_template` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`adapt_template`, `set_reference_template`, `set_offset_template`, `best_match`, `fast_match`, `best_match_rot`

Module

Matching

serialize_template (: : TemplateID : SerializedItemHandle)

Serialize a template.

serialize_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

`serialize_template` serializes the data of a template (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_template` is converted to a serialized item. The template is defined by the handle `TemplateID`. The serialized template is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_template`.

Parameters

- ▷ **TemplateID** (input_control) template $\leadsto$ handle
Handle of the template.
- ▷ **SerializedItemHandle** (output_control) serialized_item $\leadsto$ handle
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_template` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_template`, `create_template_rot`

Possible Successors

`fwrite_serialized_item`, `send_serialized_item`, `deserialize_template`

Module

Matching

set_offset_template (: : TemplateID, GrayOffset :)

Gray value offset for template.

set_offset_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

`set_offset_template` adds a gray value offset to the template to eliminate gray value changes in the image. The parameter `GrayOffset` specifies a difference relative to the gray values of the pattern when it was created with `create_template` (not relative to the last call of `set_offset_template`). The values of `GrayOffset` has to be chosen according to the gray values of the image: A brighter image results in a positive value, a darker image results in a negative value. `set_offset_template` has to be called each time the gray values of the image changes. The gray values can be measured in a reference area using `intensity` or `min_max_gray`

Parameters

- ▷ **TemplateID** (input_control) template $\leadsto$ handle
Template number.
- ▷ **GrayOffset** (input_control) number $\leadsto$ integer
Offset of gray values.
Default: 0
Suggested values: `GrayOffset` $\in$ {-10, -5, -2, -1, 0, 1, 2, 5, 10}
Value range: $-255 \leq \text{GrayOffset} \leq 255$
Minimum increment: 1
Recommended increment: 1

Result

If the parameter values are correct, the operator `set_offset_template` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TemplateID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

Matching

set_reference_template (: : TemplateID, Row, Column :)

Define reference position for a matching template.

set_reference_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

`set_reference_template` allows to define a new reference position for a template. As default after calling `create_template` or `create_template_rot` the center of gravity of the template is used. Using `set_reference_template` the reference position can be redefined. In the case of the center of gravity as reference the vector (0, 0) is returned after matching for a null translation of the pattern relative to the image.

Parameters

- ▷ **TemplateID** (input_control) template $\leadsto$ *handle*
Template number.
- ▷ **Row** (input_control) point.y $\leadsto$ *real*
Reference position of template (row).
- ▷ **Column** (input_control) point.x $\leadsto$ *real*
Reference position of template (column).

Result

If the parameter values are correct, the operator `set_reference_template` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TemplateID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

Matching

```
write_template ( : : TemplateID, FileName : )
```

Writing a template to file.

write_template is obsolete and is only provided for reasons of backward compatibility. New applications should use the shape-based or NCC-based operators instead.

The operator `write_template` writes a matching template to file which can be read again with [read_template](#). The default HALCON file extension for a template is 'gvt'.

Parameters

- ▷ **TemplateID** (input_control) template $\leadsto$ handle
Template number.
- ▷ **FileName** (input_control) filename.write $\leadsto$ string
file name.
- File extension:** .gvt

Result

If the file name is valid (permission to write), the operator `write_template` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

17.10 Morphology

```
closing_golay ( Region : RegionClosing : GolayElement, Rotation : )
```

Close a region with an element from the Golay alphabet.

closing_golay is obsolete and is only provided for reasons of backward compatibility.

`closing_golay` is defined as a Minkowski addition followed by a Minkowski subtraction. First the Minkowski addition of the input region ([Region](#)) with the structuring element from the Golay alphabet defined by [GolayElement](#) and [Rotation](#) is computed. Then the Minkowski subtraction of the result and the structuring element rotated by 180° is performed.

The following structuring elements are available:

'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number [Rotation](#) determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator [golay_elements](#).

`closing_golay` serves to close holes smaller than the structuring element, and to smooth regions' boundaries.

Attention

Not all values of `Rotation` are valid for any Golay element. For some of the values of `Rotation`, the resulting regions are identical to the input regions.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be closed.
- ▷ **RegionClosing** (output_object) region(-array) $\leadsto$ object
Closed regions.
- ▷ **GolayElement** (input_control) string $\leadsto$ string
Structuring element from the Golay alphabet.
Default: 'h'
List of values: GolayElement $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
- ▷ **Rotation** (input_control) integer $\leadsto$ integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default: 0
List of values: Rotation $\in$ {0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15}

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

$$O(6 \cdot \sqrt{F}) .$$

Result

`closing_golay` returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`, `union1`, `watersheds`, `class_ndim_norm`

Possible Successors

`reduce_domain`, `select_shape`, `area_center`, `connection`

Alternatives

`closing`

Module

Foundation

```
dilation_golay ( Region : RegionDilation : GolayElement, Iterations,
                 Rotation : )
```

Dilate a region with an element from the Golay alphabet.

`dilation_golay` is obsolete and is only provided for reasons of backward compatibility.

`dilation_golay` dilates a region with the selected element `GolayElement` from the Golay alphabet. The following structuring elements are available:

'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number `Rotation` determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator `golay_elements`. The operator works by shifting the structuring element over the region to be processed (`Region`). For all positions of the structuring element that intersect the region, the corresponding reference point (relative to the structuring element) is added to the output region. This means that the union of all translations of the structuring element within the region is computed.

The parameter `Iterations` determines the number of iterations which are to be performed with the structuring element. The result of iteration $n - 1$ is used as input for iteration n .

Attention

Not all values of `Rotation` are valid for any Golay element. For some of the values of `Rotation`, the resulting regions are identical to the input regions.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be dilated.
- ▷ **RegionDilation** (output_object) region(-array) $\leadsto$ object
Dilated regions.
- ▷ **GolayElement** (input_control) string $\leadsto$ string
Structuring element from the Golay alphabet.
Default: 'h'
List of values: `GolayElement` $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
- ▷ **Iterations** (input_control) integer $\leadsto$ integer
Number of iterations.
Default: 1
Suggested values: `Iterations` $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Value range: $1 \leq \text{Iterations}$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Rotation** (input_control) integer $\leadsto$ integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default: 0
List of values: `Rotation` $\in$ {0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15}

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

$$O(3 \cdot \sqrt{F}) .$$

Result

`dilation_golay` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Module

Foundation

```
dilation_seq ( Region : RegionDilation : GolayElement,
               Iterations : )
```

Dilate a region sequentially.

dilation_seq is obsolete and is only provided for reasons of backward compatibility.

`dilation_seq` computes the sequential dilation of the input region [Region](#) with the selected structuring element [GolayElement](#) from the Golay alphabet. This is done by executing the operator [dilation_golay](#) with all rotations of the structuring element [Iterations](#) times. The following structuring elements can be selected: 'l', 'd', 'c', 'f', 'h', 'k'.

In order to compute the skeleton of a region, usually the elements 'l' and 'm' are used. Only the “foreground elements” (even rotation numbers) are used. The elements 'i' and 'e' result in unchanged output regions. The elements 'l', 'm' and 'f2' are identical for the foreground. The Golay elements, together with all possible rotations, are described with the operator [golay_elements](#).

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ *object*
Regions to be dilated.
- ▷ **RegionDilation** (output_object) region(-array) $\leadsto$ *object*
Dilated regions.
- ▷ **GolayElement** (input_control) string $\leadsto$ *string*
Structuring element from the Golay alphabet.
Default: 'h'
List of values: `GolayElement` $\in$ {'l', 'd', 'c', 'f', 'h', 'k'}
- ▷ **Iterations** (input_control) integer $\leadsto$ *integer*
Number of iterations.
Default: 1
Suggested values: `Iterations` $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Value range: $1 \leq \text{Iterations} \text{ (lin)}$
Minimum increment: 1
Recommended increment: 1

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

$$O(\text{Iterations} \cdot 20 \cdot \sqrt{F}) .$$

Result

`dilation_seq` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

erosion_golay (`Region` : `RegionErosion` : `GolayElement`, `Iterations`,
 `Rotation` :)

Erode a region with an element from the Golay alphabet.

erosion_golay is obsolete and is only provided for reasons of backward compatibility.

`erosion_golay` erodes a region with the selected element `GolayElement` from the Golay alphabet. The following structuring elements are available:

'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number `Rotation` determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator `golay_elements`. The operator works by shifting the structuring element over the region to be processed (`Region`). For all positions of the structuring element fully contained in the region, the corresponding reference point (relative to the structuring element) is added to the output region. This means that the intersection of all translations of the structuring element within the region is computed.

The parameter `Iterations` determines the number of iterations which are to be performed with the structuring element. The result of iteration $n - 1$ is used as input for iteration n .

Attention

Not all values of `Rotation` are valid for any Golay element. For some of the values of `Rotation`, the resulting regions are identical to the input regions.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be eroded.
- ▷ **RegionErosion** (output_object) region(-array) $\leadsto$ object
Eroded regions.
- ▷ **GolayElement** (input_control) string $\leadsto$ string
Structuring element from the Golay alphabet.
Default: 'h'
List of values: `GolayElement` $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}

- ▷ **Iterations** (input_control)integer $\leadsto$ integer
 Number of iterations.
Default: 1
Suggested values: Iterations $\in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}$
Value range: $1 \leq \text{Iterations} \text{ (lin)}$
Minimum increment: 1
Recommended increment: 1
- ▷ **Rotation** (input_control)integer $\leadsto$ integer
 Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default: 0
List of values: Rotation $\in \{0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15\}$

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

$$O(3 \cdot \sqrt{F}) .$$

Result

erosion_golay returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

fitting (Region, StructElements : RegionFitted : :)

Perform a closing after an opening with multiple structuring elements.

fitting is obsolete and is only provided for reasons of backward compatibility.

fitting performs an `opening` and a `closing` successively on the input regions. The eight structuring elements normally used for this operation can be generated with the operator `gen_struct_elements`. However,

other user-defined structuring elements can also be used. Let R be the input region(s) and let M_i denote the structuring elements. Furthermore, let P be the result of the opening and Q be the final result. Then the operator can be formalized as follows:

$$P = \bigcup_{i=1}^n (R \circ M_i)$$

$$Q = \bigcap_{i=1}^n (P \bullet M_i)$$

Regions larger than the structuring elements are preserved, while small gaps are closed.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be processed.
- ▷ **StructElements** (input_object) region(-array) $\leadsto$ object
Structuring elements.
- ▷ **RegionFitted** (output_object) region(-array) $\leadsto$ object
Fitted regions.

Result

`fitting` returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_struct_elements (: StructElements : Type, Row, Column :)

Generate standard structuring elements.

gen_struct_elements is obsolete and is only provided for reasons of backward compatibility.

`gen_struct_elements` serves to generate eight structuring elements normally used in the operator `fitting`. The default value 'noise' of the parameter `Type` generates elements especially suited for the elimination of noise.

M_1

M_2

M_3

M_4

Parameters

- ▷ **StructElements** (output_object) region(-array) $\leadsto$ *object*
Generated structuring elements.
- ▷ **Type** (input_control) string $\leadsto$ *string*
Type of structuring element to generate.
Default: 'noise'
List of values: Type $\in$ {'noise'}
- ▷ **Row** (input_control) point.y $\leadsto$ *integer*
Row coordinate of the reference point.
Default: 1
Suggested values: Row $\in$ {0, 1, 10, 50, 100, 200, 300, 400}
(lin)
- ▷ **Column** (input_control) point.x $\leadsto$ *integer*
Column coordinate of the reference point.
Default: 1
Suggested values: Column $\in$ {0, 1, 10, 50, 100, 200, 300, 400}
(lin)

Result

gen_struct_elements returns 2 (H_MSG_TRUE) if all parameters are correct. Otherwise, an exception is raised.

[golay_elements](#)

Module

Foundation

```
golay_elements ( : StructElement1, StructElement2 : GolayElement,
                  Rotation, Row, Column : )
```

Generate the structuring elements of the Golay alphabet.

golay_elements is obsolete and is only provided for reasons of backward compatibility.

golay_elements generates the structuring elements from the Golay alphabet. The parameter [GolayElement](#) determines the name of the structuring element, while [Rotation](#) determines its rotation. The structuring elements are intended for use in [hit_or_miss](#): In [StructElement1](#) the structuring element for the foreground is returned, while in [StructElement2](#) the structuring element for the background is returned. [Row](#) and [Column](#) determine the reference point of the structuring element.

The rotations are numbered from 0 to 15. This does not mean, however, that there are 16 different rotations: Even values denote rotations of the foreground elements, while odd values denote rotations of the background elements.

For golay_elements only even values are accepted, and determine the Golay element for [StructElement1](#). The next larger odd value is used for [StructElement2](#). There are no rotations for the Golay elements 'h' and 'i'.

Therefore, only the values 0 and 1 are possible as “rotations” (and hence only 0 for `golay_elements`). The element ‘e’ has only four possible rotations, and hence the rotation must be between 0 and 7 (for `golay_elements` the values 0, 2, 4, or 6 must be used).

The tables below show the elements of the Golay alphabet with all possible rotations. The characters used have the following meaning:

- Foreground pixel
- Background pixel
- Don't care pixel

The names of the elements and their rotation numbers are displayed below the respective element. The elements with even number contain the foreground pixels, while the elements with odd numbers contain the background pixels.

	 h(0,1)		
	 i(0,1)		
 e(0,1)	 e(2,3)	 e(4,5)	 e(6,7)
 l(0,1)	 l(2,3)	 l(4,5)	 l(6,7)
 l(8,9)	 l(10,11)	 l(12,13)	 l(14,15)
 m(0,1)	 m(2,3)	 m(4,5)	 m(6,7)
 m(8,9)	 m(10,11)	 m(12,13)	 m(14,15)
 d(0,1)	 d(2,3)	 d(4,5)	 d(6,7)

Parameters

- ▷ **StructElement1** (output_object) region $\leadsto$ object
Structuring element for the foreground.
- ▷ **StructElement2** (output_object) region $\leadsto$ object
Structuring element for the background.
- ▷ **GolayElement** (input_control) string $\leadsto$ string
Name of the structuring element.
Default: 'l'
List of values: GolayElement $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
- ▷ **Rotation** (input_control) integer $\leadsto$ integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default: 0
List of values: Rotation $\in$ {0, 2, 4, 6, 8, 10, 12, 14}
- ▷ **Row** (input_control) point.y $\leadsto$ integer
Row coordinate of the reference point.
Default: 16
Suggested values: Row $\in$ {0, 16, 32, 128, 256}
Value range: $0 \leq \text{Row} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Column** (input_control) point.x $\leadsto$ integer
Column coordinate of the reference point.
Default: 16
Suggested values: Column $\in$ {0, 16, 32, 128, 256}
Value range: $0 \leq \text{Column} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1

Result

golay_elements returns 2 (H_MSG_TRUE) if all parameters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

```
hit_or_miss_golay ( Region : RegionHitMiss : GolayElement,
                    Rotation : )
```

Hit-or-miss operation for regions using the Golay alphabet.

hit_or_miss_golay is obsolete and is only provided for reasons of backward compatibility.

`hit_or_miss_golay` performs the hit-or-miss-transformation for the input regions `Region` (using structuring elements from the Golay alphabet). First, an erosion with the foreground of the structuring element `GolayElement` is done on the input region `Region`. Then an erosion with the background of the structuring element `GolayElement` is performed on the complement of the input region. The intersection of the two resulting regions is the result `RegionHitMiss` of `hit_or_miss_golay`. The following structuring elements are available:

'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number `Rotation` determines which rotation of the element should be used. The hit-or-miss-transformation selects precisely the points for which the conditions given by the selected Golay element are fulfilled.

Attention

Not all values of `Rotation` are valid for any Golay element.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be processed.
- ▷ **RegionHitMiss** (output_object) region(-array) $\leadsto$ object
Result of the hit-or-miss operation.
- ▷ **GolayElement** (input_control) string $\leadsto$ string
Structuring element from the Golay alphabet.
Default: 'h'
List of values: `GolayElement` $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
- ▷ **Rotation** (input_control) integer $\leadsto$ integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default: 0
List of values: `Rotation` $\in$ {0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15}

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

$$O(6 \cdot \sqrt{F}) .$$

Result

`hit_or_miss_golay` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`, `union1`, `watersheds`, `class_ndim_norm`

Possible Successors

`reduce_domain`, `select_shape`, `area_center`, `connection`

Alternatives

Module

Foundation

```
hit_or_miss_seq ( Region : RegionHitMiss : GolayElement : )
```

Hit-or-miss operation for regions using the Golay alphabet (sequential).

hit_or_miss_seq is obsolete and is only provided for reasons of backward compatibility.

[hit_or_miss_golay](#) performs the hit-or-miss-transformation for the input regions [Region](#) using all rotations of a structuring element from the Golay alphabet. The result of the operator is the union of all intermediate results of the respective rotations. The following structuring elements are available:

'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The Golay elements, together with all possible rotations, are described with the operator [golay_elements](#).

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be processed.
- ▷ **RegionHitMiss** (output_object) region(-array) $\leadsto$ object
Result of the hit-or-miss operation.
- ▷ **GolayElement** (input_control) string $\leadsto$ string
Structuring element from the Golay alphabet.
Default: 'h'
List of values: GolayElement $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}

Complexity

Let F be the area of an input region, and R be the number of rotations. Then the runtime complexity for one region is:

$$O(R \cdot 6 \cdot \sqrt{F}) .$$

Result

hit_or_miss_seq returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

```
morph_hat ( Region, StructElement : RegionMorphHat : : )
```

Compute the union of [bottom_hat](#) and [top_hat](#).

morph_hat is obsolete and is only provided for reasons of backward compatibility.

`morph_hat` computes the union of the regions that are removed by an `opening` operation with the regions that are added by a `closing` operation. Hence this is the union of the results of `top_hat` and `bottom_hat`. The position of `StructElement` does not influence the result.

Structuring elements (`StructElement`) can be generated with operators such as `gen_circle`, `gen_rectangle1`, `gen_rectangle2`, `gen_ellipse`, `draw_region`, `gen_region_polygon`, `gen_region_points`, etc.

Attention

The individual regions are processed separately.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be processed.
- ▷ **StructElement** (input_object) region $\leadsto$ object
Structuring element (position-invariant).
- ▷ **RegionMorphHat** (output_object) region(-array) $\leadsto$ object
Union of top hat and bottom hat.

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
    cout << "Reproduction of 'dilation_circle ()'" << endl;
    cout << "First = original image " << endl;
    cout << "Red   = after segmentation " << endl;
    cout << "Blue  = after erosion " << endl;

    HByteImage img("monkey");
    HWindow      w;

    HRegion      circ   = HRegion::GenCircle (10, 10, 1.5);
    HRegionArray regs   = (img >= 128).Connection();
    HRegionArray tophat = regs.TopHat (circ);
    HRegionArray bothat = regs.BottomHat (circ);
    HRegionArray unionX = tophat.Union2 (bothat);

    img.Display (w);      w.Click ();
    w.SetColor ("red");   regs.Display (w);   w.Click ();
    w.SetColor ("blue");  tophat.Display (w);  w.Click ();
    w.SetColor ("green"); bothat.Display (w);  w.Click ();
    w.SetColor ("white"); unionX.Display (w);  w.Click ();

    return (0);
}
```

Result

`morph_hat` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

morph_skeleton ([Region](#) : [RegionSkeleton](#) : :)

Compute the morphological skeleton of a region.

morph_skeleton is obsolete and is only provided for reasons of backward compatibility.

[morph_skeleton](#) computes the skeleton of the input regions ([Region](#)) using morphological transformations. The computation yields a disconnected skeleton (gaps in the diagonals) having a width of one or two pixels. The calculation uses the Golay element 'h', i.e., an 8-neighborhood. This is equivalent to the maximum-norm.

Parameters

- ▷ **Region** (input_object) [region](#)(-array) $\leadsto$ *object*
Regions to be processed.
- ▷ **RegionSkeleton** (output_object) [region](#)(-array) $\leadsto$ *object*
Resulting morphological skeleton.

Result

[morph_skeleton](#) returns 2 ([H_MSG_TRUE](#)) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: [set_system](#)('no_object_result', <[RegionResult](#)>)
- empty region: [set_system](#)('empty_region_result', <[RegionResult](#)>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Alternatives

skeleton

Module

Foundation

morph_skiz (Region : RegionSkiz : Iterations1, Iterations2 :)

Thinning of a region.

morph_skiz is obsolete and is only provided for reasons of backward compatibility.

morph_skiz first performs a sequential thinning ([thinning_seq](#)) of the input region with the element 'l' of the Golay alphabet. The number of iterations is determined by the parameter [Iterations1](#). Then a sequential thinning of the resulting region with the element 'e' of the Golay alphabet is carried out. The number of iterations for this step is determined by the parameter [Iterations2](#). The skiz operation serves to compute a kind of skeleton of the input regions, and to prune the branches of the resulting skeleton. If the skiz operation is applied to the complement of the region, the region and the resulting skeleton are separated.

If very large values or 'maximal' are passed for [Iterations1](#) or [Iterations2](#), the processing stops if no more changes occur.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be thinned.
- ▷ **RegionSkiz** (output_object) region(-array) $\leadsto$ object
Result of the skiz operator.
- ▷ **Iterations1** (input_control) integer $\leadsto$ integer / string
Number of iterations for the sequential thinning with the element 'l' of the Golay alphabet.
Default: 100
Suggested values: $\text{Iterations1} \in \{\text{'maximal'}, 0, 1, 2, 3, 5, 7, 10, 15, 20, 30, 40, 50, 70, 100, 150, 200, 300, 400\}$
Value range: $0 \leq \text{Iterations1} \text{ (lin)}$
Minimum increment: 1
Recommended increment: 1
- ▷ **Iterations2** (input_control) integer $\leadsto$ integer / string
Number of iterations for the sequential thinning with the element 'e' of the Golay alphabet.
Default: 1
Suggested values: $\text{Iterations2} \in \{\text{'maximal'}, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50\}$
Value range: $0 \leq \text{Iterations2} \text{ (lin)}$
Minimum increment: 1
Recommended increment: 1

Complexity

Let F be the area of the input region. Then the runtime complexity for one region is

$$O((\text{Iterations1} + \text{Iterations2}) \cdot 3 \cdot \sqrt{F}) .$$

Result

morph_skiz returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

opening_golay (*Region* : *RegionOpening* : *GolayElement*, *Rotation* :)

Open a region with an element from the Golay alphabet.

opening_golay is obsolete and is only provided for reasons of backward compatibility.

`opening_golay` is defined as a Minkowski subtraction followed by a Minkowski addition. First the Minkowski subtraction of the input region (*Region*) with the structuring element from the Golay alphabet defined by *GolayElement* and *Rotation* is computed. Then the Minkowski addition of the result and the structuring element rotated by 180° is performed.

The following structuring elements are available:

'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number *Rotation* determines which rotation of the element should be used, and whether the foreground (even) or background version (odd) of the selected element should be used. The Golay elements, together with all possible rotations, are described with the operator `golay_elements`.

`opening_golay` serves to eliminate regions smaller than the structuring element, and to smooth regions' boundaries.

Attention

Not all values of *Rotation* are valid for any Golay element. For some of the values of *Rotation*, the resulting regions are identical to the input regions.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ *object*
Regions to be opened.
- ▷ **RegionOpening** (output_object) region(-array) $\leadsto$ *object*
Opened regions.
- ▷ **GolayElement** (input_control) string $\leadsto$ *string*
Structuring element from the Golay alphabet.
Default: 'h'
List of values: *GolayElement* $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
- ▷ **Rotation** (input_control) integer $\leadsto$ *integer*
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default: 0
List of values: *Rotation* $\in$ {0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15}

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

$$O(6 \cdot \sqrt{F}) .$$

Result

`opening_golay` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`, `union1`, `watersheds`, `class_ndim_norm`

Module

Foundation

opening_seg (Region, StructElement : RegionOpening : :)
--

Separate overlapping regions.

opening_seg is obsolete and is only provided for reasons of backward compatibility.

The `opening_seg` operation is defined as a sequence of the following operators: `erosion1`, `connection` and `dilation1` (see example). Only one iteration is done in `erosion1` and `dilation1`.

`opening_seg` serves to separate overlapping regions whose area of overlap is smaller than `StructElement`. It should be noted that the resulting regions can overlap without actually merging (see `expand_region`). `opening_seg` uses the center of gravity as the reference point of the structuring element.

Structuring elements (`StructElement`) can be generated with operators such as `gen_circle`, `gen_rectangle1`, `gen_rectangle2`, `gen_ellipse`, `draw_region`, `gen_region_polygon`, `gen_region_points`, etc.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be opened.
- ▷ **StructElement** (input_object) region $\leadsto$ object
Structuring element (position-invariant).
- ▷ **RegionOpening** (output_object) region-array $\leadsto$ object
Opened regions.

Example

```
* Simulation of opening_seg
* opening_seg (Region, StructElement, RegionOpening) :
  erosion1 (Region, StructElement, H1, 1)
  connection (H1, H2)
  dilation1 (H2, StructElement, RegionOpening, 1)
```

Complexity

Let $F1$ be the area of the input region, and $F2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F1} \cdot \sqrt{F2} \cdot \sqrt{\sqrt{F1}}) .$$

Result

`opening_seg` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`, `union1`, `watersheds`, `class_ndim_norm`,
`gen_circle`, `gen_ellipse`, `gen_rectangle1`, `gen_rectangle2`, `draw_region`,
`gen_region_points`, `gen_region_polygon_filled`

Possible Successors

Module

Foundation

```
thickening ( Region,   StructElement1,
              StructElement2 : RegionThick : Row,   Column,   Iterations : )
```

Add the result of a hit-or-miss operation to a region.

thickening is obsolete and is only provided for reasons of backward compatibility.

`thickening` performs a thickening of the input regions using morphological operations. The operator first applies a hit-or-miss-transformation to `Region` (cf. `hit_or_miss`), and then adds the detected points to the input region. The parameter `Iterations` determines the number of iterations performed.

For the choice of the structuring elements `StructElement1` and `StructElement2`, as well as for `Row` and `Column`, the same restrictions described under `hit_or_miss` apply.

The structuring elements (`StructElement1` and `StructElement2`) can be generated by calling `golay_elements`, for example.

Attention

If the reference point is contained in `StructElement1` the input region remains unchanged.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be processed.
- ▷ **StructElement1** (input_object) region $\leadsto$ object
Structuring element for the foreground.
- ▷ **StructElement2** (input_object) region $\leadsto$ object
Structuring element for the background.

- ▷ **RegionThick** (output_object) region(-array) $\leadsto$ object
Result of the thickening operator.
- ▷ **Row** (input_control) point.y $\leadsto$ integer
Row coordinate of the reference point.
Default: 16
Suggested values: Row $\in \{0, 2, 4, 8, 16, 32, 128\}$
Value range: $0 \leq \text{Row} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Column** (input_control) point.x $\leadsto$ integer
Column coordinate of the reference point.
Default: 16
Suggested values: Column $\in \{0, 2, 4, 8, 16, 32, 128\}$
Value range: $0 \leq \text{Column} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Iterations** (input_control) integer $\leadsto$ integer
Number of iterations.
Default: 1
Suggested values: Iterations $\in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50, 70, 100, 200, 400\}$
Value range: $1 \leq \text{Iterations}$ (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let F be the area of an input region, $F1$ the area of the structuring element 1, and $F2$ the area of the structuring element 2. Then the runtime complexity for one object is:

$$O\left(\text{Iterations} \cdot \sqrt{F} \cdot \left(\sqrt{F1} + \sqrt{F2}\right)\right) .$$

Result

thickening returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

`hit_or_miss`

Module

Foundation

```
thickening_golay ( Region : RegionThick : GolayElement,
                   Rotation : )
```

Add the result of a hit-or-miss operation to a region (using a Golay structuring element).

thickening_golay is obsolete and is only provided for reasons of backward compatibility.

`thickening_golay` performs a thickening of the input regions using morphological operations and structuring elements from the Golay alphabet. The operator first applies a hit-or-miss-transformation to [Region](#) (cf. [hit_or_miss_golay](#)), and then adds the detected points to the input region. The following structuring elements are available:

'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number [Rotation](#) determines which rotation of the element should be used. The Golay elements, together with all possible rotations, are described with the operator [golay_elements](#).

Attention

Not all values of [Rotation](#) are valid for any Golay element.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be processed.
- ▷ **RegionThick** (output_object) region(-array) $\leadsto$ object
Result of the thickening operator.
- ▷ **GolayElement** (input_control) string $\leadsto$ string
Structuring element from the Golay alphabet.
Default: 'h'
List of values: GolayElement $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
- ▷ **Rotation** (input_control) integer $\leadsto$ integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default: 0
List of values: Rotation $\in$ {0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15}

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

$$O(6 \cdot \sqrt{F}) .$$

Result

`thickening_golay` returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

[reduce_domain](#), [select_shape](#), [area_center](#), [connection](#)

Alternatives

Module

Foundation

```
thickening_seq ( Region : RegionThick : GolayElement,
                  Iterations : )
```

Add the result of a hit-or-miss operation to a region (sequential).

thickening_seq is obsolete and is only provided for reasons of backward compatibility.

`thickening_seq` calculates the sequential thickening of the input regions with a structuring element from the Golay alphabet (`GolayElement`). To do so, `thickening_seq` calls the operator `thickening_golay` with all possible rotations of the structuring element `Iterations` times. The following structuring elements are available:

'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The Golay elements, together with all possible rotations, are described with the operator `golay_elements`. For all elements of the Golay alphabet, except for 'c', the foreground and background masks are exchanged in order to have an effect for them on the outer boundary of the region. The element 'c' can be used to generate the convex hull of the input region if enough iterations are performed.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be processed.
- ▷ **RegionThick** (output_object) region(-array) $\leadsto$ object
Result of the thickening operator.
- ▷ **GolayElement** (input_control) string $\leadsto$ string
Structuring element from the Golay alphabet.
Default: 'h'
List of values: `GolayElement` $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
- ▷ **Iterations** (input_control) integer $\leadsto$ integer
Number of iterations.
Default: 1
Suggested values: `Iterations` $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50, 70, 100, 200}
Value range: $1 \leq \text{Iterations (lin)}$
Minimum increment: 1
Recommended increment: 1

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

$$O(\text{Iterations} \cdot 6 \cdot \sqrt{F}) .$$

Result

`thickening_seq` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

`reduce_domain`, `select_shape`, `area_center`, `connection`

Alternatives

Module

Foundation

```
thinning ( Region,  StructElement1,
           StructElement2 : RegionThin : Row,  Column,  Iterations : )
```

Remove the result of a hit-or-miss operation from a region.

thinning is obsolete and is only provided for reasons of backward compatibility.

`thinning` performs a thinning of the input regions using morphological operations. The operator first applies a hit-or-miss-transformation to [Region](#) (cf. [hit_or_miss](#)), and then removes the detected points from the input region. The parameter [Iterations](#) determines the number of iterations performed.

For the choice of the structuring elements [StructElement1](#) and [StructElement2](#), as well as for [Row](#) and [Column](#), the same restrictions described under [hit_or_miss](#) apply.

Structuring elements ([StructElement1](#), [StructElement2](#)) can be generated with operators such as [gen_circle](#), [gen_rectangle1](#), [gen_rectangle2](#), [gen_ellipse](#), [draw_region](#), [gen_region_polygon](#), [gen_region_points](#), etc.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be processed.
- ▷ **StructElement1** (input_object) region $\leadsto$ object
Structuring element for the foreground.
- ▷ **StructElement2** (input_object) region $\leadsto$ object
Structuring element for the background.
- ▷ **RegionThin** (output_object) region(-array) $\leadsto$ object
Result of the thinning operator.
- ▷ **Row** (input_control) point.y $\leadsto$ integer
Row coordinate of the reference point.
Default: 0
Value range: $0 \leq \text{Row} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Column** (input_control) point.x $\leadsto$ integer
Column coordinate of the reference point.
Default: 0
Value range: $0 \leq \text{Column} \leq 511$ (lin)
Minimum increment: 1
Recommended increment: 1
- ▷ **Iterations** (input_control) integer $\leadsto$ integer
Number of iterations.
Default: 1
Suggested values: `Iterations` $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Value range: $1 \leq \text{Iterations}$ (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let F be the area of an input region, $F1$ the area of the structuring element 1, and $F2$ the area of the structuring element 2. Then the runtime complexity for one object is:

$$O\left(\text{Iterations} \cdot \sqrt{F} \cdot \left(\sqrt{F1} + \sqrt{F2}\right)\right) .$$

Result

`thinning` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Module

Foundation

thinning_golay (<i>Region</i> : <i>RegionThin</i> : <i>GolayElement</i> , <i>Rotation</i> :)

Remove the result of a hit-or-miss operation from a region (using a Golay structuring element).

thinning_golay is obsolete and is only provided for reasons of backward compatibility.

`thinning_golay` performs a thinning of the input regions using morphological operations and structuring elements from the Golay alphabet. The operator first applies a hit-or-miss-transformation to *Region* (cf. `hit_or_miss_golay`), and then removes the detected points from the input region. The following structuring elements are available:

'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'.

The rotation number *Rotation* determines which rotation of the element should be used. The Golay elements, together with all possible rotations, are described with the operator `golay_elements`.

Attention

Not all values of *Rotation* are valid for any Golay element.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be processed.
- ▷ **RegionThin** (output_object) region(-array) $\leadsto$ object
Result of the thinning operator.
- ▷ **GolayElement** (input_control) string $\leadsto$ string
Structuring element from the Golay alphabet.
Default: 'h'
List of values: `GolayElement` $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
- ▷ **Rotation** (input_control) integer $\leadsto$ integer
Rotation of the Golay element. Depending on the element, not all rotations are valid.
Default: 0
List of values: `Rotation` $\in$ {0, 2, 4, 6, 8, 10, 12, 14, 1, 3, 5, 7, 9, 11, 13, 15}

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

$$O(6 \cdot \sqrt{F}) .$$

Result

`thinning_golay` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

thinning_seq (Region : RegionThin : GolayElement, Iterations :)
--

Remove the result of a hit-or-miss operation from a region (sequential).

thinning_seq is obsolete and is only provided for reasons of backward compatibility.

`thinning_seq` calculates the sequential thinning of the input regions with a structuring element from the Golay alphabet (`GolayElement`). To do so, `thinning_seq` calls the operator `thinning_golay` with all possible rotations of the structuring element `Iterations` times. If `Iterations` is chosen large enough, the operator calculates the skeleton of a region if the structuring elements 'l' or 'm' are used. For the element 'c' the background and foreground are exchanged in order to have an effect on the interior boundary of a region. If a very large value or 'maximal' is passed for `Iterations` the iteration stops if no more changes occur. The following structuring elements are available:

- 'l' Skeleton, similar to `skeleton`. This structuring element is also used in `morph_skiz`.
- 'm' A skeleton with many "hairs" and multiple (parallel) branches.
- 'd' A skeleton without multiple branches, but with many gaps, similar to `morph_skeleton`.
- 'c' Uniform erosion of the region.
- 'e' One pixel wide lines are shortened. This structuring element is also used in `morph_skiz`.
- 'i' Isolated points are removed. (Only `Iterations` = 1 is useful.)
- 'f' Y-junctions are eliminated. (Only `Iterations` = 1 is useful.)
- 'f2' One pixel long branches and corners are removed. (Only `Iterations` = 1 is useful.)
- 'h' A kind of inner boundary, which, however, is thicker than the result of `boundary`, is generated. (Only `Iterations` = 1 is useful.)
- 'k' Junction points are eliminated, but also new ones are generated.

The Golay elements, together with all possible rotations, are described with the operator `golay_elements`.

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ object
Regions to be processed.
- ▷ **RegionThin** (output_object) region(-array) $\leadsto$ object
Result of the thinning operator.
- ▷ **GolayElement** (input_control) string $\leadsto$ string
Structuring element from the Golay alphabet.
Default: 'l'
List of values: GolayElement $\in$ {'l', 'm', 'd', 'c', 'e', 'i', 'f', 'f2', 'h', 'k'}
- ▷ **Iterations** (input_control) integer $\leadsto$ integer / string
Number of iterations. For 'f', 'f2', 'h' and 'i' the only useful value is 1.
Default: 20
Suggested values: Iterations $\in$ {'maximal', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 40, 50, 70, 100, 150, 200}
Value range: $1 \leq \text{Iterations} \text{ (lin)}$
Minimum increment: 1
Recommended increment: 1

Complexity

Let F be the area of an input region. Then the runtime complexity for one region is:

$$O(\text{Iterations} \cdot 6 \cdot \sqrt{F}) .$$

Result

thinning_seq returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result', <RegionResult>)`
- empty region: `set_system('empty_region_result', <RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

17.11 OCR

close_ocr (: : OcrHandle :)

Deallocation of the memory of an OCR classifier.

close_ocr is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `close_ocr` deallocates the memory of the classifier having the number `OcrHandle`. Hereby all corresponding data will be deleted. However, if necessary, they can be saved in advance using the operator `write_ocr`. The number `OcrHandle` will be invalid after the call; but later the system can use it again for new classifiers.

Attention

All data of the classifier will be deleted in main memory (not on the hard disk).

Parameters

- ▷ **OcrHandle** (input_control) ocr_box $\leadsto$ handle
ID of the OCR classifier to be deleted.

Result

If the parameter `OcrHandle` is valid, the operator `close_ocr` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `OcrHandle`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`write_ocr_trainf`

Possible Successors

`read_ocr`

Module

OCR/OCV

```
create_ocr_class_box ( : : WidthPattern, HeightPattern,
                      Interpolation, Features, Character : OcrHandle )
```

Create a new OCR-classifier.

create_ocr_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `create_ocr_class_box` creates a new OCR classifier. For a description of this classifier see operator `learn_class_box`. This classifier must then be trained with the help of the operators `traind_ocr_class_box` or `trainf_ocr_class_box`.

The parameters `WidthPattern` and `HeightPattern` indicate the size of the input-layer of the network. This size is used for the features `'projection_horizontal'`, `'projection_vertical'`, `'pixel'`, `'pixel_invar'`, and `'pixel_binary'` to transform the character to a standard size. The bigger the standard size is, the more characters can be distinguished. Hereby the amount of time necessary for the training (as well as the number of training random samples) and the time necessary for the recognition, however, will increase as well. The parameter `Interpolation` indicates the interpolation mode concerning the adaptation of characters in the image to the network. For more detailed information on this parameter see also `affine_trans_image`. The value 0 results in the same interpolation as `'nearest_neighbor'` in `affine_trans_image`, i.e., no interpolation is performed. For 1, the same behavior as `'constant'` in `affine_trans_image` is obtained, i.e., equally weighted interpolation between adjacent pixels is used. Finally, 2 results in the same interpolation as `'weighted'`, i.e., Gaussian interpolation between adjacent pixels is used. The parameter `Interpolation` must be chosen such that no aliasing occurs when the character

is scaled to the standard size. Typically, this means that `Interpolation` should be set to `1`, except in cases where the characters are scaled down by a large amount, in which case `Interpolation = 2` should be chosen. `Interpolation = 0` should only be chosen if the characters will not be scaled.

The parameter `Character` determines all the characters which have to be recognized. Normally the transmitted strings consist of one character (e.g., alphabet). But also strings of any length can be learned. The number of distinguishable characters (number of strings in `Character`) is limited to 2048.

The parameter `Features` helps to choose additional features besides gray values in order to recognize characters.

The following features are available:

`'default'` `'ratio'` and `'pixel_invar'` are selected.

`'ratio'` Ratio of the character.

`'width'` Width of the character (not invariant to scaling).

`'height'` Height of the character (not invariant to scaling).

`'zoom_factor'` Difference in size between the current character and the values of `WidthPattern` and `HeightPattern` (not invariant to scaling).

`'foreground'` Relative number of pixels in the foreground.

`'foreground_grid_9'` Relative number of foreground pixels in a 3×3 grid within the surrounding rectangle of the character.

`'foreground_grid_16'` Relative number of foreground pixels in a 4×4 grid within the surrounding rectangle of the character.

`'anisometry'` Form feature anisometry.

`'compactness'` Form feature compactness.

`'convexity'` Form feature convexity.

`'moments_region_2nd_invar'` Normed 2nd geometric moments of the region. See also `moments_region_2nd_invar`.

`'moments_region_2nd_rel_invar'` Normed 2nd relative geometric moments of the region. See also `moments_region_2nd_rel_invar`.

`'moments_region_3rd_invar'` Normed 3rd geometric moments of the region. See also `moments_region_3rd_invar`.

`'moments_central'` Normed central geometric moments of the region. See also `moments_region_central`.

`'phi'` Sine and cosine of the orientation (angle) of the character.

`'num_connect'` Number of connecting components.

`'num_holes'` Number of holes.

`'projection_horizontal'` Horizontal projection of the gray values.

`'projection_horizontal_invar'` Horizontal projection of the gray values with are automatically scaled to maximum range.

`'projection_vertical'` Vertical projection of the gray values.

`'projection_vertical_invar'` Vertical projection of the gray values with are automatically scaled to maximum range.

`'cooc'` Values of the binary cooccurrence matrix.

`'moments_gray_plane'` Normed gray value moments and the angles of the gray value level.

`'num_runs'` Number of chords in the region normed to the height.

`'chord_histo'` Frequency of the chords per row (not scale-invariant).

`'pixel'` Gray value of the character.

`'pixel_invar'` Gray values of the character with automatic maximal scaling of the gray values.

`'pixel_binary'` Region of the character as a binary image zoomed to a size of `WidthPattern` $\times$ `HeightPattern`.

`'gradient_8dir'` Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a 5×5 grid are extracted from each channel. These samples are used as features.

Parameters

- ▷ **WidthPattern** (input_control) integer $\leadsto$ integer
Width of the input layer of the network.
Default: 8
Suggested values: WidthPattern $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Value range: $1 \leq \text{WidthPattern} \leq 100$
- ▷ **HeightPattern** (input_control) integer $\leadsto$ integer
Height of the input layer of the network.
Default: 10
Suggested values: HeightPattern $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Value range: $1 \leq \text{HeightPattern} \leq 100$
- ▷ **Interpolation** (input_control) integer $\leadsto$ integer
Interpolation mode concerning scaling of characters.
Default: 1
List of values: Interpolation $\in$ {0, 1, 2}
- ▷ **Features** (input_control) string(-array) $\leadsto$ string
Additional features.
Default: 'default'
List of values: Features $\in$ {'default', 'zoom_factor', 'ratio', 'width', 'height', 'foreground', 'foreground_grid_9', 'foreground_grid_16', 'anisometry', 'compactness', 'convexity', 'moments_region_2nd_invar', 'moments_region_2nd_rel_invar', 'moments_region_3rd_invar', 'moments_central', 'phi', 'num_connect', 'num_holes', 'projection_horizontal', 'projection_vertical', 'projection_horizontal_invar', 'projection_vertical_invar', 'chord_histo', 'num_runs', 'pixel', 'pixel_invar', 'pixel_binary', 'gradient_8dir', 'cooc', 'moments_gray_plane'}
- ▷ **Character** (input_control) string-array $\leadsto$ string
All characters of a set.
Default: ['a', 'b', 'c']
- ▷ **OcrHandle** (output_control) ocr_box $\leadsto$ handle
ID of the created OCR classifier.

Result

If the parameters are correct, the operator `create_ocr_class_box` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

OCR/OCV

```
create_text_model ( : : : TextModel )
```

Create a text model.

create_text_model is obsolete and is only provided for reasons of backward compatibility. New applications should use **create_text_model_reader** instead.

`create_text_model` creates a new `TextModel` which describes the text to be segmented by `find_text`. Set and query Parameters of `TextModel` via `set_text_model_param` and `get_text_model_param`.

Calls of `create_text_model` are equivalent to (and should be replaced by) calls of `create_text_model_reader` with Mode set to 'manual'.

Parameters

▷ **TextModel** (output_control) text_model ~> handle
New text model.

Result

`create_text_model` returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

OCR/OCV

```
deserialize_ocr ( : : SerializedItemHandle : OcrHandle )
```

Deserialize a serialized OCR classifier.

deserialize_ocr is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

`deserialize_ocr` deserializes an OCR classifier, that was serialized by `serialize_ocr` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created OCR classifier with the handle `OcrHandle`.

Parameters

▷ **SerializedItemHandle** (input_control) serialized_item ~> handle
Handle of the serialized item.

▷ **OcrHandle** (output_control) ocr_box ~> handle
ID of the OCR classifier.

Result

If the parameters are valid, the operator `deserialize_ocr` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

do_ocr_multi ([Character](#), [Image](#) : : [OcrHandle](#) : [Class](#), [Confidence](#))*Classify characters.*

do_ocr_multi is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator [do_ocr_multi](#) assigns a class to every [Character](#) (character). For gray value features the gray values from the surrounding rectangles of the regions are used. The gray values will be taken from the parameter [Image](#). For each character the corresponding class will be returned in [Class](#) and a confidence value will be returned in [Confidence](#). The confidence value indicates the similarity between the input pattern and the assigned character.

Parameters

- ▷ **Character** (input_object) [region](#)(-array) $\leadsto$ *object*
Characters to be recognized.
- ▷ **Image** (input_object) [singlechannelimage](#) $\leadsto$ *object* : [byte](#) / [uint2](#)
Gray values for the characters.
- ▷ **OcrHandle** (input_control) [ocr_box](#) $\leadsto$ *handle*
ID of the OCR classifier.
- ▷ **Class** (output_control) [string](#)(-array) $\leadsto$ *string*
Class (name) of the characters.
Number of elements: [Class](#) == [Character](#)
- ▷ **Confidence** (output_control) [real](#)(-array) $\leadsto$ *real*
Confidence values of the characters.
Number of elements: [Confidence](#) == [Character](#)

Result

If the input parameters are correct, the operator [do_ocr_single](#) returns the value 2 ([H_MSG_TRUE](#)). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

OCR/OCV

```
do_ocr_single ( Character, Image : : OcrHandle : Classes,  
                Confidences )
```

Classify one character.

do_ocr_single is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `do_ocr_single` assigns classes to the [Character](#) (characters). For gray value features gray values of the surrounding rectangles of the regions will be used. The gray values will be taken from the parameter [Image](#). For each character the two classes with the highest confidences will be returned in [Classes](#). The corresponding confidences will be returned in [Confidences](#). The confidence value indicates the similarity between the input pattern and the assigned character.

Parameters

- ▷ **Character** (input_object) region $\leadsto$ object
Character to be recognized.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Gray values of the characters.
- ▷ **OcrHandle** (input_control) ocr_box $\leadsto$ handle
ID of the OCR classifier.
- ▷ **Classes** (output_control) string-array $\leadsto$ string
Classes (names) of the characters.
Number of elements: 2
- ▷ **Confidences** (output_control) real-array $\leadsto$ real
Confidence values of the characters.
Number of elements: 2

Result

If the input parameters are correct, the operator `do_ocr_single` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

OCR/OCV

```
info_ocr_class_box ( : : OcrHandle : WidthPattern, HeightPattern,  
                    Interpolation, WidthMaxChar, HeightMaxChar, Features, Characters )
```

Get information about an OCR classifier.

info_ocr_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `info_ocr_class_box` returns some information about an OCR classifier. The parameters are equivalent to those of [create_ocr_class_box](#). The parameters [WidthMaxChar](#) and [HeightMaxChar](#) indicate the extension of the largest trained character. These values can be used to control the segmentation.

Parameters

- ▷ **OcrHandle** (input_control) ocr_box $\leadsto$ handle
ID of the OCR classifier.
- ▷ **WidthPattern** (output_control) integer $\leadsto$ integer
Width of the scaled characters.
- ▷ **HeightPattern** (output_control) integer $\leadsto$ integer
Height of the scaled characters.
- ▷ **Interpolation** (output_control) integer $\leadsto$ integer
Interpolation mode for scaling the characters.
- ▷ **WidthMaxChar** (output_control) integer $\leadsto$ integer
Width of the largest trained character.
- ▷ **HeightMaxChar** (output_control) integer $\leadsto$ integer
Height of the largest trained character.
- ▷ **Features** (output_control) string-array $\leadsto$ string
Used features.
- ▷ **Characters** (output_control) string-array $\leadsto$ string
All characters of the set.

Result

The operator `info_ocr_class_box` always returns 2 (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

OCR/OCV

ocr_change_char (: : OcrHandle, Character :)

Define a new conversion table for the characters.

ocr_change_char is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `ocr_change_char` establishes a new look-up table for the characters. Hereby the number of strings of `Character` must be the same as of the classifier `OcrHandle`. In order to enlarge the font, the operator `ocr_change_char` may be used as follows: More characters than actually needed will be indicated when creating a network using (`create_ocr_class_box`). The last n characters will not be used so far. If more characters are needed at a later stage, these unused characters will be allocated and then trained with the help of the operator `ocr_change_char`.

Parameters

- ▷ **OcrHandle** (input_control) ocr_box $\leadsto$ handle
ID of the OCR-network to be changed.
- ▷ **Character** (input_control) string-array $\leadsto$ string
New assign of characters.
Default: ['a','b','c']

Result

If the number of characters in `Character` is identical with the number of the characters of the network, the operator `ocr_change_char` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `OcrHandle`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`read_ocr`

Possible Successors

`do_ocr_multi_class_mlp`, `do_ocr_single_class_mlp`

Module

OCR/OCV

ocr_get_features (<code>Character</code> : : <code>OcrHandle</code> : <code>FeatureVector</code>)
--

Access the features which correspond to a character.

ocr_get_features is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `ocr_get_features` calculates the features for the given `Character`. The type and number of features is determined by the classifier `OcrHandle`. `FeatureVector` contains the same values which are used inside operators like `traind_ocr_class_box` or `trainf_ocr_class_box`.

Parameters

- ▷ **Character** (input_object)singlechannelimage $\leadsto$ object : byte / uint2
Characters to be trained.
- ▷ **OcrHandle** (input_control) ocr_box $\leadsto$ handle
ID of the desired OCR-classifier.
- ▷ **FeatureVector** (output_control) real-array $\leadsto$ real
Feature vector.

Result

If the parameters are correct, the operator `ocr_get_features` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`read_ocr`, `reduce_domain`, `threshold`, `connection`

See also

`trainf_ocr_class_box`, `traind_ocr_class_box`

Module

OCR/OCV

```
read_ocr ( : : FileName : OcrHandle )
```

Read an OCR classifier from a file.

read_ocr is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `read_ocr` reads an OCR classifier from a file `FileName`. This file will hereby be searched in the directory (\$HALCONROOT/ocr/) as well as in the currently used directory. If too many classifiers have been loaded, an error message will be displayed.

Parameters

- ▷ **FileName** (input_control) filename.read $\leadsto$ string
Name of the OCR classifier file.
Default: 'testnet'
File extension: .obc, .fnt
- ▷ **OcrHandle** (output_control) ocr_box $\leadsto$ handle
ID of the read OCR classifier.

Result

If the indicated file is available and the format is correct, the operator `read_ocr` returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`reset_obj_db`

Possible Successors

`do_ocr_multi`, `do_ocr_single`, `traind_ocr_class_box`, `trainf_ocr_class_box`

Module

OCR/OCV

```
serialize_ocr ( : : OcrHandle : SerializedItemHandle )
```

Serialize an OCR classifier.

serialize_ocr is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

`serialize_ocr` serializes an OCR classifier (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_ocr` is converted to a serialized item. The OCR classifier is defined by the handle `OcrHandle`. The serialized OCR classifier is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ocr`.

Parameters

- ▷ **OcrHandle** (input_control) ocr_box $\leadsto$ handle
ID of the OCR classifier.
- ▷ **SerializedItemHandle** (output_control) serialized_item $\leadsto$ handle
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_ocr` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`traind_ocr_class_box`, `trainf_ocr_class_box`

Possible Successors

Module

OCR/OCV

<pre>testd_ocr_class_box (Character, Image : : OcrHandle, Class : Confidence)</pre>
--

Test an OCR classifier.

`testd_ocr_class_box` is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `testd_ocr_class_box` tests the confidence with which a character belongs to a given class. Any number of regions of an image can be passed. For each character (region) in `Character` the corresponding name (class) `Class` must be specified. The gray values are passed in `Image`. When the operator has finished the parameter `Confidence` provides information about how sure a character belongs to the (arbitrary chosen) class.

Parameters

- ▷ **Character** (input_object) region(-array) $\leadsto$ *object*
Characters to be tested.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ *object* : byte / uint2
Gray values for the characters.
- ▷ **OcrHandle** (input_control) ocr_box $\leadsto$ *handle*
ID of the desired OCR-classifier.
- ▷ **Class** (input_control) string(-array) $\leadsto$ *string*
Class (name) of the characters.
Default: 'a'
- ▷ **Confidence** (output_control) real(-array) $\leadsto$ *real*
Confidence for the character to belong to the class.

Result

If the parameters are correct, the operator `testd_ocr_class_box` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[read_ocr](#), [trainf_ocr_class_box](#), [traind_ocr_class_box](#)

Module

OCR/OCV

```
traind_ocr_class_box ( Character, Image : : OcrHandle,
    Class : AvgConfidence )
```

Train an OCR classifier by the input of regions.

traind_ocr_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `traind_ocr_class_box` trains the classifier directly via the input of regions in an image. Any number of regions of an image can be passed. For each character (region) in [Character](#) the corresponding name (class) [Class](#) must be specified. The gray values are passed in [Image](#). When the procedure has finished the parameter [AvgConfidence](#) provides information about the success of the training: It contains the average confidence of the trained characters measured by a re-classification. The confidence of mismatched characters is set to 0 (thus, the average confidence will be decreased significantly).

Parameters

- ▷ **Character** (input_object) region(-array) $\leadsto$ *object*
Characters to be trained.
- ▷ **Image** (input_object) singlechannelimage $\leadsto$ *object* : byte / uint2
Gray values for the characters.
- ▷ **OcrHandle** (input_control) ocr_box $\leadsto$ *handle*
ID of the desired OCR-classifier.
- ▷ **Class** (input_control) string(-array) $\leadsto$ *string*
Class (name) of the characters.
Default: 'a'
- ▷ **AvgConfidence** (output_control) real $\leadsto$ *real*
Average confidence during a re-classification of the trained characters.

Result

If the parameters are correct, the operator `traind_ocr_class_box` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OcrHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

[create_ocr_class_box](#), [read_ocr](#)

Possible Successors

[write_ocr](#), [do_ocr_multi](#), [do_ocr_single](#)

Alternatives

[trainf_ocr_class_box](#)

Module

OCR/OCV

```
trainf_ocr_class_box ( : : OcrHandle,
    TrainingFile : AvgConfidence )
```

Train an OCR classifier with the help of a training file.

trainf_ocr_class_box is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `trainf_ocr_class_box` trains the classifier `OcrHandle` via the indicated training files. Any number of files can be indicated. The parameter `AvgConfidence` provides information about the success of the training: It contains the average confidence of the trained characters measured by a re-classification. The confidence of mismatched characters is set to 0 (thus, the average confidence will be decreased significantly). Please, note that training characters that have no corresponding class in the classifier `OcrHandle` are discarded.

Attention

The names of the characters in the file must fit the network.

Parameters

- ▷ **OcrHandle** (input_control) `ocr_box` $\leadsto$ *handle*
ID of the desired OCR-network.
- ▷ **TrainingFile** (input_control) `filename.read(-array)` $\leadsto$ *string*
Names of the training files.
Default: 'train_ocr'
File extension: .trf, .otr
- ▷ **AvgConfidence** (output_control) *real* $\leadsto$ *real*
Average confidence during a re-classification of the trained characters.

Result

If the file name is correct and the data fit the network, the operator `trainf_ocr_class_box` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `OcrHandle`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_ocr_class_box`, `read_ocr`

Possible Successors

`traind_ocr_class_box`, `write_ocr`, `do_ocr_multi`, `do_ocr_single`

Alternatives

`traind_ocr_class_box`

Module

OCR/OCV

```
write_ocr ( : : OcrHandle, FileName : )
```

Writing an OCR classifier into a file.

write_ocr is obsolete and is only provided for reasons of backward compatibility. New applications should use the MLP, SVM or CNN based operators instead.

The operator `write_ocr` writes the OCR classifier `OcrHandle` into the file `FileName`. Since the data of the classifier will be lost when the program is finished, they have to be stored after the training if the user wants to use them again at a later execution of the program. The data can then be read with the help of the operator `read_ocr`. The extension will be added automatically to the parameter `FileName`.

Attention

The output file `FileName` must be given without extension.

Parameters

- ▷ **OcrHandle** (input_control) `ocr_box` $\leadsto$ *handle*
ID of the OCR classifier.
- ▷ **FileName** (input_control) `filename.write` $\leadsto$ *string*
Name of the file for the OCR classifier (without extension).
Default: 'my_ocr'
File extension: .obc

Result

If the parameter `OcrHandle` is valid and the indicated file can be written, the operator `write_ocr` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`traind_ocr_class_box`, `trainf_ocr_class_box`

Possible Successors

Module

OCR/OCV

17.12 Regions

get_region_chain (Region : : : Row, Column, Chain)

Contour of an object as chain code.

get_region_chain is obsolete and is only provided for reasons of backward compatibility.

The operator `get_region_chain` returns the contour of a region. A contour is a series of pixels describing the outline of the region. The contour “lies on” the region. It starts at the smallest line number; in that line at the pixel with the largest column index. The rotation occurs clockwise. Holes of the region are ignored. The direction code (chain code) is defined as follows:

3	2	1
4	*	0
5	6	7

The operator `get_region_chain` returns the code in the form of a tuple. In case of an empty region the parameters `Row` and `Column` are zero and `Chain` is the empty tuple.

Attention

Holes of the region are ignored. Only one region may be passed, and it must have exactly one connection component.

Parameters

- ▷ **Region** (input_object) region $\leadsto$ object
Region to be transformed.
- ▷ **Row** (output_control) chain.begin.y $\leadsto$ integer
Line of starting point.
- ▷ **Column** (output_control) chain.begin.x $\leadsto$ integer
Column of starting point.
- ▷ **Chain** (output_control) chain.code-array $\leadsto$ integer
Direction code of the contour (from starting point).
Value range: $0 \leq \text{Chain} \leq 7$

Result

The operator `get_region_chain` normally returns the value 2 (`H_MSG_TRUE`). If more than one connection component is passed an exception is raised. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result', <Result>)`. The behavior in case of empty region (the region is the empty set) is set via the operator `set_system('empty_region_result', <Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`sobel_amp`, `threshold`, `skeleton`, `edges_image`, `gen_rectangle1`, `gen_circle`

Possible Successors

See also

`copy_obj`, `get_region_contour`, `get_region_polygon`

Module

Foundation

hamming_change_region (InputRegion : OutputRegion : Width, Height, Distance :)

Generate a region having a given Hamming distance.

hamming_change_region is obsolete and is only provided for reasons of backward compatibility.

`hamming_change_region` changes the region in the left upper part of the image given by `Width` and `Height` such that the resulting regions have a Hamming distance of `Distance` to the input regions. This is done by adding or removing `Distance` points from the input region.

Attention

If `Width` and `Height` are chosen too large the resulting region requires a lot of memory.

Parameters

- ▷ **InputRegion** (input_object) region(-array) $\leadsto$ object
Region to be modified.
- ▷ **OutputRegion** (output_object) region(-array) $\leadsto$ object
Regions having the required Hamming distance.
- ▷ **Width** (input_control) extent.x $\leadsto$ integer
Width of the region to be changed.
Default: 100
Suggested values: `Width` $\in$ {64, 128, 256, 512}
Value range: $1 \leq \text{Width} \leq 512$ (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: `Width` > 0

- ▷ **Height** (input_control) extent.y $\leadsto$ integer
 Height of the region to be changed.
Default: 100
Suggested values: Height $\in$ {64, 128, 256, 512}
Value range: $1 \leq \text{Height} \leq 512$ (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Height > 0
- ▷ **Distance** (input_control) integer $\leadsto$ integer
 Hamming distance between the old and new regions.
Default: 1000
Suggested values: Distance $\in$ {100, 500, 1000, 5000, 10000}
Value range: $0 \leq \text{Distance} \leq 10000$ (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Distance ≥ 0 && Distance < Width * Height

Complexity

Memory requirement of the generated region (worst case): $O(2 * \text{Width} * \text{Height})$.

Result

hamming_change_region returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`connection`, `regiongrowing`, `pouring`, `class_ndim_norm`

Possible Successors

`select_shape`

See also

`hamming_distance`

Module

Foundation

interjacent (Region : RegionInterjacent : Mode :)
--

Partition the image plane using given regions.

interjacent is obsolete and is only provided for reasons of backward compatibility.

`interjacent` partitions the image plane using the regions given in `Region`. The result is a region containing the extracted separating lines. The following modes of operation can be used:

'medial_axis' This mode is used for regions that do not touch or overlap. The operator will find separating lines between the regions which partition the background evenly between the input regions. This corresponds to the following calls:

Example:

```
complement('full', Region, Tmp)
skeleton(Tmp, Result)
```

'border' If the input regions do not touch or overlap this mode is equivalent to `boundary(Region, Result)`, i.e., it replaces each region by its boundary. If regions are touching they are aggregated into one region. The corresponding output region then contains the boundary of the aggregated region, as well as the one pixel wide separating line between the original regions. This corresponds to the following calls:

Example:

```
boundary (Region, Tmp1, 'inner')
union1 (Tmp1, Tmp2)
skeleton (Tmp2, Result)
```

'mixed' In this mode the operator behaves like the mode *'medial_axis'* for non-overlapping regions. If regions touch or overlap, again separating lines between the input regions are generated on output, but this time including the “touching line” between regions, i.e., touching regions are separated by a line in the output region. This corresponds to the following calls:

Example:

```
erosion1 (Region, Mask, Tmp1, 1)
union1 (Tmp1, Tmp2)
complement (full, Tmp2, Tmp3)
skeleton (Tmp3, Result)
```

where Mask denotes the following “cross mask”:

```
      ×
    × × ×
      ×
```

Parameters

- ▷ **Region** (input_object) region(-array) $\leadsto$ *object*
Regions for which the separating lines are to be determined.
 - ▷ **RegionInterjacent** (output_object) region $\leadsto$ *object*
Output region containing the separating lines.
 - ▷ **Mode** (input_control) string $\leadsto$ *string*
Mode of operation.
- Default:** 'mixed'
- List of values:** Mode $\in$ {'medial_axis', 'border', 'mixed'}

Example

```
read_image (Image, 'forest_air1')
mean_image (Image, Mean, 31, 31)
dyn_threshold (Image, Mean, Seg, 20, 'light')
interjacent (Seg, Graph, 'medial_axis')
dev_display (Graph)
```

Result

interjacent always returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result', <Result>)`, the behavior in case of an empty input region via `set_system('empty_region_result', <Result>)`, and the behavior in case of an empty result region via `set_system('store_empty_region', '<true>'/'false')>`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`threshold`, `connection`, `regiongrowing`, `pouring`

Possible Successors

`select_shape`, `disp_region`

See also

`expand_region`, `junctions_skeleton`, `boundary`

Module

Foundation

17.13 Segmentation

```
bin_threshold ( Image : Region : : )
```

Segment an image using an automatically determined threshold.

bin_threshold is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator [binary_threshold](#) instead.

bin_threshold segments a single-channel gray value image using an automatically determined threshold. First, the relative histogram of the gray values is determined. Then, relevant minima are extracted from the histogram, which are used as parameters for a thresholding operation. In order to reduce the number of minima, the histogram is smoothed with a Gaussian, as in [auto_threshold](#). The mask size is enlarged until there is only one minimum in the smoothed histogram. The selected region contains the pixels with gray values from 0 to the minimum or for real images from the smallest value to the respective minimum. This operator is, for example useful for the segmentation of dark characters on a light paper.

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ object : byte / uint2 / real
Input image.
- ▷ **Region** (output_object) region(-array) $\leadsto$ object
Dark regions of the image.

Example

```
read_image (Image, 'letters')
bin_threshold (Image, Seg)
connection (Seg, Connected)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Module

Foundation

```
class_ndim_box ( MultiChannelImage : Regions : ClassifHandle : )
```

Classify pixels using hyper-cuboids.

class_ndim_box is obsolete and is only provided for reasons of backward compatibility.

class_ndim_box classifies the pixels of the multi-channel image given in [MultiChannelImage](#). To do so, the classifier [ClassifHandle](#) created with [create_class_box](#) is used. The classifier can be trained using [learn_ndim_box](#) or as described with [create_class_box](#). More information on the structure of the classifier can be found also under that operator.

[MultiChannelImage](#) is a multi channel image. Its pixel values are used for the classification.

Parameters

- ▷ **MultiChannelImage** (input_object) (multichannel-)image(-array) $\leadsto$ object : byte / direction /
cyclic / int1 / int2 / int4 / real
Multi channel input image.
- ▷ **Regions** (output_object) region-array $\leadsto$ object
Classification result.
- ▷ **ClassifHandle** (input_control) class_box $\leadsto$ handle
Handle of the classifier.

Example

```

read_image(Image, 'montery')
dev_display(Image)
dev_set_color('green')
disp_message(WindowHandle, 'Draw learning region ', \
              'window', 12, 12, 'black', 'true')
draw_region(Reg1, WindowHandle)
reduce_domain(Image, Reg1, Foreground)
dev_set_color('red')
disp_message(WindowHandle, 'Draw background region', \
              'window', 12, 12, 'black', 'true')
draw_region(Reg2, WindowHandle)
reduce_domain(Image, Reg2, Background)
disp_message(WindowHandle, 'Training... ', \
              'window', 12, 12, 'black', 'true')
create_class_box(ClassifHandle)
learn_ndim_box(Foreground, Background, Image, ClassifHandle)
disp_message(WindowHandle, 'Classification ', \
              'window', 12, 12, 'black', 'true')
class_ndim_box(Image, Res, ClassifHandle)
dev_set_draw('fill')
dev_display(Res)
close_class_box(ClassifHandle)

```

Complexity

Let N be the number of hyper-cuboids and A be the area of the input region. Then the runtime complexity is $O(N, A)$.

Result

`class_ndim_box` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags `'no_object_result'`, `'empty_region_result'`, and `'store_empty_region'` with [set_system](#). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```

expand_line ( Image : RegionExpand : Coordinate, ExpandType,
               RowColumn, Threshold : )

```

Expand a region starting at a given line.

expand_line is obsolete and is only provided for reasons of backward compatibility.

`expand_line` generates a region by expansion, starting at a given line (row or column). The expansion is terminated when the current gray value differs by more than `Threshold` from the mean gray value along the line (`ExpandType = 'mean'`) or from the previously added gray value (`ExpandType = 'gradient'`).

Parameters

- ▷ **Image** (input_object) singlechannelimage(-array) $\leadsto$ *object* : byte
Input image.
- ▷ **RegionExpand** (output_object) region(-array) $\leadsto$ *object*
Extracted segments.
- ▷ **Coordinate** (input_control) integer $\leadsto$ *integer*
Row or column coordinate.
Default: 256
Suggested values: `Coordinate` $\in$ {16, 64, 128, 200, 256, 300, 400, 511}
Restriction: `Coordinate` $\geq$ 0
- ▷ **ExpandType** (input_control) string $\leadsto$ *string*
Stopping criterion.
Default: 'gradient'
List of values: `ExpandType` $\in$ {'gradient', 'mean'}
- ▷ **RowColumn** (input_control) string $\leadsto$ *string*
Segmentation mode (row or column).
Default: 'row'
List of values: `RowColumn` $\in$ {'row', 'column'}
- ▷ **Threshold** (input_control) number $\leadsto$ *real* / *integer*
Threshold for the expansion.
Default: 3.0
Suggested values: `Threshold` $\in$ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 13.0, 17.0, 20.0, 30.0}
Value range: $0 \leq \text{Threshold} \leq 255$ (lin)
Minimum increment: 1.0
Recommended increment: 1.0

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
    HImage    image (argv[1]),
              gauss;
    HWindow   win;

    win.SetDraw ("margin");
    win.SetColored (12);

    image.Display (win);

    gauss = image.GaussImage (5);

    HRegionArray reg = gauss.ExpandLine (100, "mean", "row", 5.0);

    reg.Display (win);
    win.Click ();

    return (0);
}
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

```
learn_ndim_box ( Foreground, Background,
                  MultiChannelImage : : ClassifHandle : )
```

Train a classifier using a multi-channel image.

learn_ndim_box is obsolete and is only provided for reasons of backward compatibility.

`learn_ndim_box` trains the classifier `ClassifHandle` with the gray values of `MultiChannelImage` using the points in `Foreground` as training sample. The points in `Background` are to be rejected by the classifier. The classifier trained thus can be used in `class_ndim_box` to segment multi-channel images. `Foreground` are the points that should be found, `Background` contains the points that should not be found.

Each pixel is trained once during the training process. For points in `Foreground` the class “0” is used, while for `Background` “1” is used. Pixels are trained by alternating points from `Foreground` with points from `Background`. If one region is smaller than the other, pixels are taken cyclically from the smaller region until the larger region is exhausted. `learn_ndim_box` later accepts only points that can be classified into class “0”.

From a user’s point of view the key difference between `learn_ndim_norm` and `learn_ndim_box` is that in the latter case the rejection class affects the classification process itself. Here, a hyper plane is generated that separates `Foreground` and `Background` classes, so that no points in feature space are classified incorrectly. As for `learn_ndim_norm`, however, an overlap between `Foreground` and `Background` class is allowed. This has its effect on the return value `Quality`. The larger the overlap, the smaller this value.

Attention

All channels must be of the same type.

Parameters

- ▷ **Foreground** (input_object) region(-array) $\leadsto$ object
Foreground pixels to be trained.
- ▷ **Background** (input_object) region(-array) $\leadsto$ object
Background pixels to be trained (rejection class).
- ▷ **MultiChannelImage** (input_object) (multichannel-)image(-array) $\leadsto$ object : byte / direction /
cyclic / int1 / int2 / int4 / real
Multi-channel training image.
- ▷ **ClassifHandle** (input_control) class_box $\leadsto$ handle
Handle of the classifier.

Complexity

Let N be the number of generated hyper-cuboids and A be the area of the larger input region. Then the runtime complexity is $O(N * A)$.

Result

`learn_ndim_box` returns 2 (`H_MSG_TRUE`) if all parameters are correct and there is an active classifier. The

behavior with respect to the input images can be determined by setting the values of the flags 'no_object_result' and 'empty_region_result' with `set_system`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassifHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_class_box`, `draw_region`

Possible Successors

`class_ndim_box`, `descript_class_box`

Alternatives

`learn_class_box`, `learn_ndim_norm`

17.14 Tools

```
approx_chain ( : : Row, Column, MinWidthCoord, MaxWidthCoord,
    ThreshStart, ThreshEnd, ThreshStep, MinWidthSmooth,
    MaxWidthSmooth, MinWidthCurve, MaxWidthCurve, Weight1, Weight2,
    Weight3 : ArcCenterRow, ArcCenterCol, ArcAngle, ArcBeginRow,
    ArcBeginCol, LineBeginRow, LineBeginCol, LineEndRow, LineEndCol,
    Order )
```

Approximate a contour by arcs and lines.

approx_chain is obsolete and is only provided for reasons of backward compatibility.

The coordinates of a curve are approximated by a row of lines and arcs. The procedure tries values from a user-definable range for certain parameters. The limits of these ranges are explicitly stated in the parameter list of the function (MinWidthCoord ... MaxWidthCoord, ThreshStart ... ThreshEnd, MinWidthSmooth ... MaxWidthSmooth, MinWidthCurve ... MaxWidthCurve). Additionally, the step width for the parameter area of the threshold value for pointed corners has to be indicated (ThreshStep). By narrowing the covered areas the runtime of the calculation can be shortened, but the result may deteriorate.

The parameters Weight1, Weight2 and Weight3 indicate whether the desired weighting is placed more on precision of the approximation, obtaining as much large segments as possible or as few small segments as possible. Thus, for (Weight1, Weight2, Weight3) (1,0,0) creates a very precise approximation and (0,1,1) an approximation with as few large segments as possible.

The result of the procedure is returned separately as arcs and lines. If one is interested in the sequence of the segments the individual resulting elements can be read successively from the resulting tuples; the sequence can be taken from the return parameter order (0: next element is next line segment, 1: next element is next arc segment).

Attention

Contours which can possibly consist of only one segment should also be examined with a threshold maximum (ThreshEnd) > 1.0, because otherwise at least one "corner point" is determined in any case.

Parameters

- ▷ **Row** (input_control) point.y-array $\leadsto$ integer
Row of the contour.
Default: 32
- ▷ **Column** (input_control) point.x-array $\leadsto$ integer
Column of the contour.
Default: 32
- ▷ **MinWidthCoord** (input_control) real $\leadsto$ real
Minimum width of Gauss operator for coordinate smoothing (> 0.4).
Default: 0.5
Suggested values: MinWidthCoord $\in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}$
Value range: $0.4 \leq \text{MinWidthCoord} \leq 3.0$ (lin)
Minimum increment: 0.01
Recommended increment: 0.1
- ▷ **MaxWidthCoord** (input_control) real $\leadsto$ real
Maximum width of Gauss operator for coordinate smoothing (> 0.4).
Default: 2.4
Suggested values: MaxWidthCoord $\in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}$
Value range: $0.4 \leq \text{MaxWidthCoord} \leq 3.0$ (lin)
Minimum increment: 0.01
Recommended increment: 0.1
- ▷ **ThreshStart** (input_control) real $\leadsto$ real
Minimum threshold value of the curvature for accepting a corner (relative to the largest curvature present).
Default: 0.3
Suggested values: ThreshStart $\in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8\}$
Value range: $0.1 \leq \text{ThreshStart} \leq 0.9$ (lin)
Minimum increment: 0.01
Recommended increment: 0.1
- ▷ **ThreshEnd** (input_control) real $\leadsto$ real
Maximum threshold value of the curvature for accepting a corner (relative to the largest curvature present).
Default: 0.9
Suggested values: ThreshEnd $\in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8\}$
Value range: $0.1 \leq \text{ThreshEnd} \leq 0.9$ (lin)
Minimum increment: 0.01
Recommended increment: 0.1
- ▷ **ThreshStep** (input_control) real $\leadsto$ real
Step width for threshold increase.
Default: 0.2
Suggested values: ThreshStep $\in \{0.3, 0.4, 0.5\}$
Value range: $0.1 \leq \text{ThreshStep} \leq 0.9$ (lin)
Minimum increment: 0.01
Recommended increment: 0.1
- ▷ **MinWidthSmooth** (input_control) real $\leadsto$ real
Minimum width of Gauss operator for smoothing the curvature function (> 0.4).
Default: 0.5
Suggested values: MinWidthSmooth $\in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}$
Value range: $0.4 \leq \text{MinWidthSmooth} \leq 3.0$ (lin)
Minimum increment: 0.01
Recommended increment: 0.1
- ▷ **MaxWidthSmooth** (input_control) real $\leadsto$ real
Maximum width of Gauss operator for smoothing the curvature function.
Default: 2.4
Suggested values: MaxWidthSmooth $\in \{0.5, 0.7, 1.0, 1.2, 1.5, 1.7\}$
Value range: $0.4 \leq \text{MaxWidthSmooth} \leq 3.0$ (lin)
Minimum increment: 0.01
Recommended increment: 0.1

- ▷ **MinWidthCurve** (input_control)integer $\rightsquigarrow$ integer
Minimum width of curve area for curvature determination (> 0.4).
Default: 2
Suggested values: MinWidthCurve $\in \{2, 5, 7\}$
Value range: $1 \leq \text{MinWidthCurve} \leq 12$ (lin)
Minimum increment: 1
Recommended increment: 2
- ▷ **MaxWidthCurve** (input_control)integer $\rightsquigarrow$ integer
Maximum width of curve area for curvature determination.
Default: 12
Suggested values: MaxWidthCurve $\in \{2, 5, 7\}$
Value range: $1 \leq \text{MaxWidthCurve} \leq 20$ (lin)
Minimum increment: 1
Recommended increment: 2
- ▷ **Weight1** (input_control)real $\rightsquigarrow$ real
Weighting factor for approximation precision.
Default: 1.0
Suggested values: Weight1 $\in \{0.0, 0.5, 1.0\}$
Value range: $0.0 \leq \text{Weight1} \leq 1.0$ (lin)
Minimum increment: 0.1
Recommended increment: 0.5
- ▷ **Weight2** (input_control)real $\rightsquigarrow$ real
Weighting factor for large segments.
Default: 1.0
Suggested values: Weight2 $\in \{0.0, 0.5, 1.0\}$
Value range: $0.0 \leq \text{Weight2} \leq 1.0$ (lin)
Minimum increment: 0.1
Recommended increment: 0.5
- ▷ **Weight3** (input_control)real $\rightsquigarrow$ real
Weighting factor for small segments.
Default: 1.0
Suggested values: Weight3 $\in \{0.0, 0.5, 1.0\}$
Value range: $0.0 \leq \text{Weight3} \leq 1.0$ (lin)
Minimum increment: 0.1
Recommended increment: 0.5
- ▷ **ArcCenterRow** (output_control) arc.center.y-array $\rightsquigarrow$ integer
Row of the center of an arc.
- ▷ **ArcCenterCol** (output_control) arc.center.x-array $\rightsquigarrow$ integer
Column of the center of an arc.
- ▷ **ArcAngle** (output_control) arc.angle.rad-array $\rightsquigarrow$ real
Angle of an arc.
- ▷ **ArcBeginRow** (output_control) arc.begin.y-array $\rightsquigarrow$ integer
Row of the starting point of an arc.
- ▷ **ArcBeginCol** (output_control) arc.begin.x-array $\rightsquigarrow$ integer
Column of the starting point of an arc.
- ▷ **LineBeginRow** (output_control) line.begin.y-array $\rightsquigarrow$ integer
Row of the starting point of a line segment.
- ▷ **LineBeginCol** (output_control) line.begin.x-array $\rightsquigarrow$ integer
Column of the starting point of a line segment.
- ▷ **LineEndRow** (output_control) line.end.y-array $\rightsquigarrow$ integer
Row of the ending point of a line segment.
- ▷ **LineEndCol** (output_control) line.end.x-array $\rightsquigarrow$ integer
Column of the ending point of a line segment.
- ▷ **Order** (output_control) integer-array $\rightsquigarrow$ integer
Sequence of line (value 0) and arc segments (value 1).

Example

```

/* read edge image */
read_image(&Image,"fig1_kan");
/* construct edge region */
hysteresis_threshold(Image,&RK1,64,255,40,1);
connection(RK1,&Rand);
/* fetch chain code */
T_get_region_contour(Rand,&Rows,&Columns);
firstline = get_i(Tline,0);
firstcol = get_i(Tcol,0);
/* approximation with lines and circular arcs */
set_d(t1,0.4,0);
set_d(t2,2.4,0);

set_d(t3,0.3,0);
set_d(t4,0.9,0);

set_d(t5,0.2,0);

set_d(t6,0.4,0);
set_d(t7,2.4,0);

set_i(t8,2,0);
set_i(t9,12,0);

set_d(t10,1.0,0);
set_d(t11,1.0,0);
set_d(t12,1.0,0);

T_approx_chain(Rows,Columns,t1,t2,t3,t4,t5,t6,t7,t8,t9,t10,t11,t12,
               &Bzl,&Bzc,&Br,&Bwl,&Bwc,&Ll0,&Lc0,&Ll1,&Lc1,&order);
nob = length_tuple(Bzl);
nol = length_tuple(Ll0);
/* draw lines and arcs */
set_i(WindowHandleTuple,WindowHandle,0);
set_line_width(WindowHandle,4);
if (nob>0) T_disp_arc(Bzl,Bzc,Br,Bwl,Bwc);
set_line_width(WindowHandle,1);
if (nol>0) T_disp_line(WindowHandleTuple,Ll0,Lc0,Ll1,Lc1);

```

Result

The operator `approx_chain` returns the value 2 (`H_MSG_TRUE`) if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
approx_chain_simple ( : : Row, Column : ArcCenterRow,
    ArcCenterCol, ArcAngle, ArcBeginRow, ArcBeginCol, LineBeginRow,
    LineBeginCol, LineEndRow, LineEndCol, Order )
```

Approximate a contour by arcs and lines.

approx_chain_simple is obsolete and is only provided for reasons of backward compatibility.

The contour of a curve is approximated by a sequence of lines and arcs.

The result of the procedure is returned separately as arcs and lines. If one is interested in the sequence of the segments the individual resulting elements can be read successively from the resulting tuples. The sequence can be taken from the return parameter order (0: next element is next line segment, 1: next element is next arc segment).

The operator `approx_chain_simple` behaves similarly as `approx_chain` except that in the case of `approx_chain_simple` the missing parameters are internally allocated as follows: `MinWidthCoord` = 1.0, `MaxWidthCoord` = 3.0, `ThreshStart` = 0.5, `ThreshEnd` = 0.9, `ThreshStep` = 0.3, `MinWidthSmooth` = 1.0, `MaxWidthSmooth` = 3.0, `MinWidthCurve` = 2, `MaxWidthCurve` = 9, `Weight1` = 1.0, `Weight2` = 1.0, `Weight3` = 1.0.

Parameters

- ▷ **Row** (input_control) point.y-array $\leadsto$ *integer*
Row of the contour.
Default: 32
- ▷ **Column** (input_control) point.x-array $\leadsto$ *integer*
Column of the contour.
Default: 32
- ▷ **ArcCenterRow** (output_control) arc.center.y-array $\leadsto$ *integer*
Row of the center of an arc.
- ▷ **ArcCenterCol** (output_control) arc.center.x-array $\leadsto$ *integer*
Column of the center of an arc.
- ▷ **ArcAngle** (output_control) arc.angle.rad-array $\leadsto$ *real*
Angle of an arc.
- ▷ **ArcBeginRow** (output_control) arc.begin.y-array $\leadsto$ *integer*
Row of the starting point of an arc.
- ▷ **ArcBeginCol** (output_control) arc.begin.x-array $\leadsto$ *integer*
Column of the starting point of an arc.
- ▷ **LineBeginRow** (output_control) line.begin.y-array $\leadsto$ *integer*
Row of the starting point of a line segment.
- ▷ **LineBeginCol** (output_control) line.begin.x-array $\leadsto$ *integer*
Column of the starting point of a line segment.
- ▷ **LineEndRow** (output_control) line.end.y-array $\leadsto$ *integer*
Row of the ending point of a line segment.
- ▷ **LineEndCol** (output_control) line.end.x-array $\leadsto$ *integer*
Column of the ending point of a line segment.
- ▷ **Order** (output_control) integer-array $\leadsto$ *integer*
Sequence of line (value 0) and arc segments (value 1).

Example

```
/* read edge image */
read_image (&Image, "fig1_kan");
/* construct edge region */
hysteresis_threshold (Image, &RK1, 64, 255, 40, 1);
connection (RK1, &Rand);
/* fetch chain code */
T_get_region_contour (Rand, &Rows, &Columns);
```

```

firstline = get_i(Tline,0);
firstcol = get_i(Tcol,0);
/* approximation with lines and circular arcs */
T_approx_chain_simple(Rows,Columns,
                      &Bzl,&Bzc,&Br,&Bwl,&Bwc,&Ll0,&Lc0,&Ll1,&Lc1,&order);
nob = length_tuple(Bzl);
nol = length_tuple(Ll0);
/* draw lines and arcs */
set_i(WindowHandleTuple,WindowHandle,0);
set_line_width(WindowHandle,4);
if (nob>0) T_disp_arc(Bzl,Bzc,Br,Bwl,Bwc);
set_line_width(WindowHandle,1);
if (nol>0) T_disp_line(WindowHandleTuple,Ll0,Lc0,Ll1,Lc1);

```

Result

The operator `approx_chain_simple` returns the value 2 (`H_MSG_TRUE`) if the parameters are correct. Otherwise an exception is raised.

clear_all_data_code_2d_models (: : :)
--

This operator is inoperable. It had the following function: Delete all 2D data code models and free the allocated memory.

clear_all_data_code_2d_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_data_code_2d_models**, the operator will be removed in future versions.

.

Attention

clear_all_data_code_2d_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_data_code_2d_models** *must not* be used in any application.

Result

The operator **clear_all_data_code_2d_models** returns the value 2 (H_MSG_TRUE) if all 2D data code models were freed correctly. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Data Code

clear_all_deformable_models (: : :)
--

This operator is inoperable. It had the following function: Free the memory of all deformable models.

clear_all_deformable_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_deformable_models**, the operator will be removed in future versions.

.

Attention

`clear_all_deformable_models` exists solely for the purpose of implementing the “reset program” functionality in HDevelop. `clear_all_deformable_models` *must not* be used in any application.

Result

`clear_all_deformable_models` always returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

<code>clear_all_descriptor_models</code> (: : :)

This operator is inoperable. It had the following function: Free the memory of all descriptor models in RAM.

`clear_all_descriptor_models` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `clear_all_descriptor_models`, the operator will be removed in future versions.

.

Result

If the operator is successful, `clear_descriptor_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

<code>clear_all_events</code> (: : :)
--

This operator is inoperable. It had the following function: Clear all event synchronization objects.

`clear_all_events` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `clear_all_events`, the operator will be removed in future versions.

.

Attention

`clear_all_events` exists solely for the purpose of implementing the “reset program” functionality in HDevelop. `clear_all_events` *must not* be used in any application.

Result

`clear_all_events` returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

Foundation

clear_all_lexica (: : :)

This operator is inoperable. It had the following function: Clear all lexica.

clear_all_lexica is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_lexica**, the operator will be removed in future versions.

.

Attention

clear_all_lexica exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_lexica** *must not* be used in any application.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

clear_all_matrices (: : :)

This operator is inoperable. It had the following function: Clear all matrices from memory.

clear_all_matrices is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_matrices**, the operator will be removed in future versions.

.

Attention

clear_all_matrices exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_matrices** *must not* be used in any application.

Result

clear_all_matrices always returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

clear_all_metrology_models (: : :)

This operator is inoperable. It had the following function: Delete all metrology models and free the allocated memory.

clear_all_metrology_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_metrology_models**, the operator will be removed in future versions.

.

Attention

clear_all_metrology_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_metrology_models** *must not* be used in any application.

Result

The operator **clear_all_metrology_models** returns the value 2 (H_MSG_TRUE) if all metrology models were freed correctly. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

clear_all_mutexes (: : :)

This operator is inoperable. It had the following function: Clear all mutex synchronization objects.

clear_all_mutexes is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_mutexes**, the operator will be removed in future versions.

.

Attention

clear_all_mutexes exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_mutexes** *must not* be used in any application.

Result

clear_all_mutexes returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

clear_all_ncc_models (: : :)

This operator is inoperable. It had the following function: Free the memory of all NCC models.

clear_all_ncc_models is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **clear_all_ncc_models**, the operator will be removed in future versions.

.

Attention

clear_all_ncc_models exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **clear_all_ncc_models** *must not* be used in any application.

Result

`clear_all_ncc_models` always returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

<code>clear_all_object_model_3d (: : :)</code>
--

This operator is inoperable. It had the following function: Free the memory of all 3D object models.

`clear_all_object_model_3d` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `clear_all_object_model_3d`, the operator will be removed in future versions.

.

Attention

`clear_all_object_model_3d` exists solely for the purpose of implementing the “reset program” functionality in HDevelop. `clear_all_object_model_3d` *must not* be used in any application.

Result

`clear_all_object_model_3d` always returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

<code>clear_all_ocr_class_knn (: : :)</code>
--

This operator is inoperable. It had the following function: Clear all OCR classifiers.

`clear_all_ocr_class_knn` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `clear_all_ocr_class_knn`, the operator will be removed in future versions.

.

Attention

`clear_all_ocr_class_knn` exists solely for the purpose of implementing the “reset program” functionality in HDevelop. `clear_all_ocr_class_knn` *must not* be used in any application.

Result

`clear_all_ocr_class_knn` always returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Matching

close_all_bg_esti (: : :)

This operator is inoperable. It had the following function: Delete all background estimation data sets.

close_all_bg_esti is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **close_all_bg_esti**, the operator will be removed in future versions.

.

Attention

close_all_bg_esti exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **close_all_bg_esti** *must not* be used in any application.

Result

If it is possible to close the background estimation data sets the operator **close_all_bg_esti** returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

close_all_class_box (: : :)

This operator is inoperable. It had the following function: Destroy all classifiers.

close_all_class_box is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **close_all_class_box**, the operator will be removed in future version.

.

Attention

close_all_class_box exists solely for the purpose of implementing the “reset program” functionality in HDevelop. **close_all_class_box** *must not* be used in any application.

Result

If it is possible to close the classifiers the operator **close_all_class_box** returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

close_all_files (: : :)

This operator is inoperable. It had the following function: Close all open files.

close_all_files is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use **close_all_files**, the operator will be removed in future version.

.

Attention

`close_all_files` exists solely for the purpose of implementing the “reset program” functionality in HDevelop. `close_all_files` *must not* be used in any application.

Result

If it is possible to close the files the operator `close_all_files` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

<code>close_all_framegrabbers</code> (: : :)

This operator is inoperable. It had the following function: Close all image acquisition devices.

`close_all_framegrabbers` is obsolete, inoperable, and is only provided for reasons of backward compatibility. New applications should not use `close_all_framegrabbers`, the operator will be removed in future versions.

.

Attention

`close_all_framegrabbers` exists solely for the purpose of implementing the “reset program” functionality in HDevelop. `close_all_framegrabbers` *must not* be used in any application.

Result

If it is possible to close all image acquisition devices, the operator `close_all_framegrabbers` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
filter_kalman ( : : Dimension, Model, Measurement,
                PredictionIn : PredictionOut, Estimate )
```

Estimate the current state of a system with the help of the Kalman filtering.

filter_kalman is obsolete and is only provided for reasons of backward compatibility.

The operator **filter_kalman** returns an estimate of the current state (or also a prediction of a future state) of a discrete, stochastically disturbed, linear system. In practice, Kalman filters are used successfully in image processing in the analysis of image sequences (background identification, lane tracking with the help of line tracing or region analysis, etc.). A short introduction concerning the theory of the Kalman filters will be followed by a detailed description of the routine **filter_kalman** itself.

KALMAN FILTER: A discrete, stochastically disturbed, linear system is characterized by the following markers:

- State $x(t)$: Describes the current state of the system (speeds, temperatures,...).
- Parameter $u(t)$: Inputs from outside into the system.

- Measurement $y(t)$: Measurements gained by observing the system. They indicate the state of the system (or at least parts of it).
- An output function describing the dependence of the measurements on the state.
- A transition function indicating how the state changes with regard to time, the current value and the parameters.

The output function and the transition function are linear. Their application can therefore be written as a multiplication with a matrix.

The transition function is described with the help of the transition matrix $A(t)$ and the parameter matrix $G(t)$, the initial function is described by the measurement matrix $C(t)$. Hereby $C(t)$ characterizes the dependency of the new state on the old, $G(t)$ indicates the dependency on the parameters. In practice it is rarely possible (or at least too time consuming) to describe a real system and its behavior in a complete and exact way. Normally only a relatively small number of variables will be used to simulate the behavior of the system. This leads to an error, the so called system error (also called system disturbance) $v(t)$.

The output function, too, is usually not exact. Each measurement is faulty. The measurement errors will be called $w(t)$. Therefore the following system equations arise:

$$\begin{aligned}x(t+1) &= A(t)x(t) + G(t)u(t) + v(t) \\ y(t) &= c(t)x(t) + w(t)\end{aligned}$$

The system error $v(t)$ and the measurement error $w(t)$ are not known. As far as systems are concerned which are interpreted with the help of the Kalman filter, these two errors are considered as Gaussian distributed random vectors (therefore the expression “stochastically disturbed systems”). Therefore the system can be calculated, if the corresponding expected values for $v(t)$ and $w(t)$ as well as the covariance matrices are known.

The estimation of the state of the system is carried out in the same way as in the Gaussian-Markov-estimation. However, the Kalman filter is a recursive algorithm which is based only on the current measurements $y(t)$ and the latest state $x(t)$. The latter implicitly also includes the knowledge about earlier measurements.

A suitable estimate value x_0 , which is interpreted as the expected value of a random variable for $x(0)$, must be indicated for the initial value $x(0)$. This variable should have an expected error value of 0 and the covariance matrix P_0 which also has to be indicated. At a certain time t the expected values of both disturbances $v(t)$ and $w(t)$ should be 0 and their covariances should be $Q(t)$ and $R(t)$. $x(t)$, $v(t)$ and $w(t)$ will usually be assumed to be not correlated (any kind of noise-process can be modelled - however the development of the necessary matrices by the user will be considerably more demanding). The following conditions must be met by the searched estimate values x^t :

- The estimate values x^t are linearly dependent on the actual value $x(t)$ and on the measurement sequence $y(0), y(1), \dots, y(t)$.
- x^t being hereby considered to meet its expectations, i.e. $Ex^t = Ex(t)$.
- The grade criterion for x^t is the criterion of minimal variance, i.e. the variance of the estimation error defined as $x(t) - x^t$, being as small as possible.

After the initialization

$$\hat{x}(0) = x_0, \hat{P}(0) = P_0$$

at each point in time t the Kalman filter executes the following calculation steps:

$$\begin{aligned}(K - III) \quad K(t) &= \frac{\hat{P}(t)C'(t)}{C(t)\hat{P}(t)C'(t) + R(t)} \\ (K - IV) \quad x^t &= \hat{x}(t) + K(t)(y(t) - C(t)\hat{x}(t)) \\ (K - V) \quad \tilde{P}(t) &= \hat{P}(t) - K(t)C(t)\hat{P}(t) \\ (K - I) \quad \hat{x}(t+1) &= A(t)x^t + G(t)u(t) \\ (K - II) \quad \hat{P}(t+1) &= A(t)\tilde{P}(t)A'(t) + Q(t)\end{aligned}$$

Hereby $\tilde{P}(t)$ is the covariance matrix of the estimation error, $\hat{x}(t)$ is the extrapolation value respective the prediction value of the state, $\hat{P}(t)$ are the covariances of the prediction error $\hat{x} - x$, K is the amplifier matrix (the so called Kalman gain), and X' is the transposed of a matrix X .

Please note that the prediction of the future state is also possible with the equation (K-I). Sometimes this is very useful in image processing in order to determine “regions of interest” in the next image.

As mentioned above, it is much more demanding to model any kind of noise processes. If for example the system noise and the measurement noise are correlated with the corresponding covariance matrix L , the equations for the Kalman gain and the error covariance matrix have to be modified:

$$\begin{aligned} (K - III) \quad K(t) &= \frac{\hat{P}(t)C'(t)+L(t)}{C(t)\hat{P}(t)+C(t)L(t)+L'C'(t)+R(t)} \\ (K - V) \quad \tilde{P}(t) &= (\hat{P}(t) - K(t)C(t)\hat{P}(t))\hat{P}(t) - K(t)L(t) \end{aligned}$$

This means that the user himself has to establish the linear system equations from (K-I) up to (K-V) with respect to the actual problem. The user must therefore develop a mathematical model upon which the solution to the problem can be based. Statistical characteristics describing the inaccuracies of the system as well as the measurement errors, which are to be expected, thereby have to be estimated if they cannot be calculated exactly. Therefore the following individual steps are necessary:

1. Developing a mathematical model
2. Selecting characteristic state variables
3. Establishing the equations describing the changes of these state variables and their linearization (matrices A and G)
4. Establishing the equations describing the dependency of the measurement values of the system on the state variables and their linearization (matrix C)
5. Developing or estimating of statistical dependencies between the system disturbances (matrix Q)
6. Developing or estimating of statistical dependencies between the measurement errors (matrix R)
7. Initialization of the initial state

As mentioned above, the initialization of the system (point 7) hereby necessitates to indicate an estimate x_0 of the state of the system at the time 0 and the corresponding covariance matrix P_0 . If the exact initial state is not known, it is recommendable to set the components of the vector x_0 to the average values of the corresponding range, and to set high values for P_0 (about the size of the squares of the range). After a few iterations (when the number of the accumulated measurement values in total has exceeded the number of the system values), the values which have been determined in this way are also usable.

If on the other hand the initial state is known exactly, all entries for P_0 have to be set to 0, because P_0 describes the covariances of the error between the estimated value x_0 and the actual value $x(0)$.

THE FILTER ROUTINE:

A Kalman filter is dependent on a range of data which can be organized in four groups:

Model parameter: transition matrix A , control matrix G including the parameter u and the measurement matrix C

Model stochastic: system-error covariance matrix Q , system-error - measurement-error covariance matrix L , and measurement-error covariance matrix R

Measurement vector: y

History of the system: extrapolation vector $\hat{x}$ and extrapolation-error covariance matrix $\hat{P}$

Thereby many systems can work without input “from outside”, i.e. without G and u . Further, system errors and measurement errors are normally not correlated (L is dropped).

Actually the data necessary for the routine will be set by the following parameters:

Dimension: This parameter includes the dimensions of the status vector, the measurement vector and the controller vector. **Dimension** thereby is a vector $[n,m,p]$, whereby ‘ n ’ indicates the number of the state variables, ‘ m ’ the number of the measurement values and ‘ p ’ the number of the controller members. For a system without determining control (i.e. without influence “from outside”) therefore $[n,m,0]$ has to be passed.

Model: This parameter includes the lined up matrices (vectors) ‘ A,C,Q,G,u ’ and (if necessary) ‘ L ’ having been stored in row-major order. **Model** therefore is a vector of the length $n \times n + n \times m + n \times n + n \times p + p [+n \times m]$. The last summand is dropped, in case the system errors and measurement errors are not correlated, i.e. there is no value for ‘ L ’.

Measurement: This parameter includes the matrix ' R ' which has been stored in row-major order, and the measurement vector ' y ' lined up. **Measurement** therefore is a vector of the dimension $m \times m + m$.

PredictionIn / PredictionOut: These two parameters include the matrix $\hat{P}$ (the extrapolation-error covariance matrix) which has been stored in row-major order and the extrapolation vector $\hat{x}$ lined up. This means, they are vectors of the length $n \times n + n$. **PredictionIn** therefore is an input parameter, which must contain $\hat{P}(t)$ and $\hat{x}(t)$ at the current time t . With **PredictionOut** the routine returns the corresponding predictions $\hat{P}(t+1)$ and $\hat{x}(t+1)$.

Estimate: With this parameter the routine returns the matrix $\tilde{P}$ (the estimation-error covariance matrix) which has been stored in row-major order and the estimated state $\tilde{x}$ lined up. **Estimate** therefore is a vector of the length $n \times n + n$.

Please note that the covariance matrices ($Q, R, \hat{P}, \tilde{P}$) must of course be symmetric.

Parameters

- ▷ **Dimension** (input_control) integer-array $\leadsto$ integer
The dimensions of the state vector, the measurement and the controller vector.
Default: [3,1,0]
Value range: $0 \leq \text{Dimension} \leq 30$
- ▷ **Model** (input_control) real-array $\leadsto$ real
The lined up matrices A, C, Q , possibly G and u , and if necessary L which have been stored in row-major order.
Default: [1.0,1.0,0.5,0.0,1.0,1.0,0.0,0.0,1.0,1.0,0.0,0.0,54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]
Value range: $0.0 \leq \text{Model} \leq 10000.0$
- ▷ **Measurement** (input_control) real-array $\leadsto$ real
The matrix R stored in row-major order and the measurement vector y lined up.
Default: [1.2,1.0]
Value range: $0.0 \leq \text{Measurement} \leq 10000.0$
- ▷ **PredictionIn** (input_control) real-array $\leadsto$ real
The matrix $\hat{P}$ (the extrapolation-error covariances) stored in row-major order and the extrapolation vector $\hat{x}$ lined up.
Default: [0.0,0.0,0.0,0.0,180.5,0.0,0.0,0.0,100.0,0.0,100.0,0.0]
Value range: $0.0 \leq \text{PredictionIn} \leq 10000.0$
- ▷ **PredictionOut** (output_control) real-array $\leadsto$ real
The matrix P^* (the extrapolation-error covariances) stored in row-major order and the extrapolation vector $\hat{x}$ lined up.
- ▷ **Estimate** (output_control) real-array $\leadsto$ real
The matrix $\tilde{P}$ (the estimation-error covariances) stored in row-major order and the estimated state $\tilde{x}$ lined up.

Example

```
* Typical procedure:
* To initialize the variables, which describe the model, e.g., with
read_kalman('kalman.init',Dim,Mod,Meas,Pred)

* Generation of the first measurements (typical of the first image of an
* image series) with an appropriate problem-specific procedure (there is a
* fictitious procedure extract_features in example):
* extract_features(Image1,Meas,Meas1)

* first Kalman-Filtering:
filter_kalman(Dim,Mod,Meas1,Pred,Pred1,Est1)

* To use the estimate value (if need be the prediction too)
* with a problem-specific procedure (here use_est):
* use_est(Est1)

* To get the next measurements (e.g., from the next image):
* extract_next_features(Image2,Meas1,Meas2)
```

```
* if need be Update of the model parameter (a constant model)
* second Kalman-Filtering:
filter_kalman (Dim,Mod,Meas2,Pred1,Pred2,Est2)
* use_est (Est2)
* extract_next_features (Image3,Meas2,Meas3)
* etc.
```

Result

If the parameter values are correct, the operator `filter_kalman` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

<pre>intersection_ll (: : RowA1, ColumnA1, RowA2, ColumnA2, RowB1, ColumnB1, RowB2, ColumnB2 : Row, Column, IsParallel)</pre>
--

Calculate the intersection point of two lines.

intersection_ll is obsolete and is only provided for reasons of backward compatibility. New applications should use the operator **intersection_lines** of the chapter Tools / Geometry instead.

The operator `intersection_ll` calculates the intersection point of two lines. As input the two points on each line are expected (`RowA1,ColumnA1,RowA2,ColumnA2`) and (`RowB1,ColumnB1,RowB2,ColumnB2`). The parameters `Row` and `Column` return the result of the calculation. If the lines are parallel, the values of `Row` and `Column` are undefined and `IsParallel` is 1. Otherwise, `IsParallel` is 0.

Attention

If the lines are parallel the values of `Row` and `Column` are undefined.

Parameters

- ▷ **RowA1** (input_control) point.y(-array) $\leadsto$ *real* / integer
Row coordinate of the first point of the first line.
- ▷ **ColumnA1** (input_control) point.x(-array) $\leadsto$ *real* / integer
Column coordinate of the first point of the first line.
- ▷ **RowA2** (input_control) point.y(-array) $\leadsto$ *real* / integer
Row coordinate of the second point of the first line.
- ▷ **ColumnA2** (input_control) point.x(-array) $\leadsto$ *real* / integer
Column coordinate of the second point of the first line.
- ▷ **RowB1** (input_control) point.y(-array) $\leadsto$ *real* / integer
Row coordinate of the first point of the second line.
- ▷ **ColumnB1** (input_control) point.x(-array) $\leadsto$ *real* / integer
Column coordinate of the first point of the second line.
- ▷ **RowB2** (input_control) point.y(-array) $\leadsto$ *real* / integer
Row coordinate of the second point of the second line.
- ▷ **ColumnB2** (input_control) point.x(-array) $\leadsto$ *real* / integer
Column coordinate of the second point of the second line.
- ▷ **Row** (output_control) point.y(-array) $\leadsto$ *real*
Row coordinate of the intersection point.
- ▷ **Column** (output_control) point.x(-array) $\leadsto$ *real*
Column coordinate of the intersection point.
- ▷ **IsParallel** (output_control) number(-array) $\leadsto$ *integer*
Are the two lines parallel?

Example

```

dev_set_color ('black')
RowLine1 := 350
ColLine1 := 250
RowLine2 := 300
ColLine2 := 300
Rows := 300
Columns := 50
disp_line (WindowHandle, RowLine1, ColLine1, RowLine2, ColLine2)
n := 0
for Rows := 40 to 200 by 4
    dev_set_color ('red')
    disp_line (WindowHandle, Rows, Columns, Rows+n, Columns+n)
    intersection_ll (Rows, Columns, Rows+n, Columns+n, RowLine1, ColLine1, \
                    RowLine2, ColLine2, Row, Column, IsParallel)
    dev_set_color ('blue')
    disp_line (WindowHandle, Row, Column-2, Row, Column+2)
    disp_line (WindowHandle, Row-2, Column, Row+2, Column)
    n := n+8
endfor

```

Result

intersection_ll returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
partition_lines ( : : RowBeginIn, ColBeginIn, RowEndIn, ColEndIn,
    Feature, Operation, Min, Max : RowBeginOut, ColBeginOut,
    RowEndOut, ColEndOut, FailRowBOut, FailColBOut, FailRowEOut,
    FailColEOut )
```

Partition lines according to various criteria.

partition_lines is obsolete and is only provided for reasons of backward compatibility.

The operator `partition_lines` divides lines into two sets according to various criteria. For each input line the indicated features (`Feature`) are calculated. If each (`Operation = 'and'`) or at least one (`Operation = 'or'`) of the calculated features is within the given limits (`Min,Max`) the line is transferred into the first set (parameters `RowBeginOut` to `ColEndOut`), otherwise into the second set (parameters `FailRowBOut` to `FailColEOut`). The default values `'min'` and `'max'` of the parameters `Min` and `Max` are used to leave bottom and top limit, respectively, open.

Condition: $Min_i \leq Feature_i(Line) \leq Max_i$

Possible values for `Feature`:

'length' (Euclidean) length of the line

'row' Line index of the center

'column' Column index of the center

'phi' Orientation of the line ($-\frac{\pi}{2} < \varphi \leq \frac{\pi}{2}$)

Attention

If only one feature is used the value of `Operation` is meaningless. Several features are processed according to the sequence in which they are passed.

Parameters

- ▷ **RowBeginIn** (input_control) line.begin.y-array $\leadsto$ integer
Row coordinates of the starting points of the input lines.
- ▷ **ColBeginIn** (input_control) line.begin.x-array $\leadsto$ integer
Column coordinates of the starting points of the input lines.
- ▷ **RowEndIn** (input_control) line.end.y-array $\leadsto$ integer
Row coordinates of the ending points of the input lines.
- ▷ **ColEndIn** (input_control) line.end.x-array $\leadsto$ integer
Column coordinates of the ending points of the input lines.
- ▷ **Feature** (input_control) string(-array) $\leadsto$ string
Features to be used for selection.
List of values: `Feature` $\in$ {`'length'`, `'row'`, `'column'`, `'phi'`}
- ▷ **Operation** (input_control) string $\leadsto$ string
Desired combination of the features.
List of values: `Operation` $\in$ {`'and'`, `'or'`}
- ▷ **Min** (input_control) string(-array) $\leadsto$ string / integer / real
Lower limits of the features or `'min'`.
Default: `'min'`
- ▷ **Max** (input_control) string(-array) $\leadsto$ string / integer / real
Upper limits of the features or `'max'`.
Default: `'max'`
- ▷ **RowBeginOut** (output_control) line.begin.y-array $\leadsto$ integer
Row coordinates of the starting points of the lines fulfilling the conditions.
- ▷ **ColBeginOut** (output_control) line.begin.x-array $\leadsto$ integer
Column coordinates of the starting points of the lines fulfilling the conditions.
- ▷ **RowEndOut** (output_control) line.end.y-array $\leadsto$ integer
Row coordinates of the ending points of the lines fulfilling the conditions.
- ▷ **ColEndOut** (output_control) line.begin.x-array $\leadsto$ integer
Column coordinates of the ending points of the lines fulfilling the conditions.

- ▷ **FailRowBOut** (output_control) line.begin.y-array $\leadsto$ *integer*
Row coordinates of the starting points of the lines not fulfilling the conditions.
- ▷ **FailColBOut** (output_control) line.begin.x-array $\leadsto$ *integer*
Column coordinates of the starting points of the lines not fulfilling the conditions.
- ▷ **FailRowEOut** (output_control) line.end.y-array $\leadsto$ *integer*
Row coordinates of the ending points of the lines not fulfilling the conditions.
- ▷ **FailColEOut** (output_control) line.end.x-array $\leadsto$ *integer*
Column coordinates of the ending points of the lines not fulfilling the conditions.

Result

The operator `partition_lines` returns the value 2 (H_MSG_TRUE) if the parameter values are correct. Otherwise an exception is raised.

Module

Foundation

```
read_kalman ( : : FileName : Dimension, Model, Measurement,
              Prediction )
```

Read the description file of a Kalman filter.

read_kalman is obsolete and is only provided for reasons of backward compatibility.

The operator `read_kalman` reads the description file `FileName` of a Kalman filter. Kalman filters return an estimate of the current state (or even the prediction of a future state) of a discrete, stochastically disturbed, linear system. They are successfully used in image processing, especially in the analysis of image sequences. A Kalman filtering is based on a mathematical model of the system to be examined which at any point in time has the following characteristics:

Model parameter: transition matrix A , control matrix G including the controller output u and the measurement matrix C

Model stochastic: system-error covariance matrix Q , system-error - measurement-error covariance matrix L and measurement-error covariance matrix R

Estimate of the initial state of the system: state x_0 and corresponding covariance matrix P_0

Many systems do not need entries “from outside”, and therefore G and u can be dropped. Further, system errors and measurement errors are normally not correlated (L is dropped). The characteristics mentioned above can be stored in an ASCII-file and then can be read with the help of the operator `read_kalman`. This ASCII-file must have the following structure:

Dimension row

+ content row

+ matrix A

```

+ matrix C
+ matrix Q
[ + matrix G + vector u ]
[ + matrix L ]
+ matrix R
[ + matrix P0 ]
[ + vector x0 ]

```

The dimension row thereby is always of the following form:

$$n = \langle \text{integer} \rangle \quad m = \langle \text{integer} \rangle \quad p = \langle \text{integer} \rangle$$

whereby n indicates the number of the state variables, m the number of the measurement values and p the number of the controller members (see also [Dimension](#)). The maximal dimension will hereby be limited by a system constant (= 30 for the time being).

The content row has the following form:

$$A * C * Q * G * u * L * R * P * x *$$

and describes the following content of the file. Instead of '*', '+' (= parameter is available) respectively '-' (= parameter is missing) have to be set. Please note that only the parameters marked by [...] in the above list may be left out in the description file. If the initial state estimate a_0 is missing (i.e. 'x-'), the components of the vector will supposed to be 0.0. If the covariance matrix P_0 of the initial state estimate is missing (i.e. 'P-'), the error will be supposed to be tremendous. In this case the matrix elements will be set to 10000.0. This value seems to be very high, however, it is only sufficient if the range of components of the state vector x is smaller to the tenth power. ($r \times s$) matrices will be stored per row in the following form:

$$\begin{array}{cccc}
 & \langle \text{comment, i.e. string} \rangle & & \\
 \langle a_{11} \rangle & \langle a_{12} \rangle & \cdots & \langle a_{1s} \rangle \\
 \vdots & & \ddots & \vdots \\
 \langle a_{r1} \rangle & \langle a_{r2} \rangle & \cdots & \langle a_{rs} \rangle
 \end{array}$$

(the spaces and line feed characters can be chosen at will),

vectors will be stored correspondingly in the following form:

$$\begin{array}{ccc}
 \langle \text{comment, i.e. string} \rangle & & \\
 \langle a_1 \rangle & \cdots & \langle a_k \rangle
 \end{array}$$

The following parameter values are returned by the operator `read_kalman`:

Dimension: This parameter includes the dimensions of the status vector, the measurement vector and the controller vector. [Dimension](#) thereby is a vector $[n, m, p]$, whereby ' n ' indicates the number of the state variables, ' m ' the number of the measurement values and ' p ' the number of the controller members. For a system without determining control (i.e. without influence "from outside") therefore [Dimension](#) = $[n, m, 0]$.

Model: This parameter includes the lined up matrices (vectors) ' A , C , Q , G , u ' and (if necessary) ' L ' having been stored in row-major order. [Model](#) therefore is a vector of the length $n \times n + n \times m + n \times n + n \times p + p[+n \times m]$. The last summand is dropped, in case the system errors and measurement errors are not correlated, i.e. there is no value for ' L '.

Measurement: This parameter includes the matrix ' R ' which has been stored in row-major order. [Measurement](#) therefore is vector of the dimension $m \times m$.

Prediction: This parameter includes the matrix ' P_0 ' (the error covariance matrix of the initial state estimate) and the initial state estimate ' x_0 ' lined up. This means, it is a vector of the length $n \times n + n$.

Parameters

- ▷ **FileName** (input_control)filename.read $\rightsquigarrow$ string
Description file for a Kalman filter.
Default: 'kalman.init'
- ▷ **Dimension** (output_control)integer-array $\rightsquigarrow$ integer
The dimensions of the state vector, the measurement vector and the controller vector.

- ▷ **Model** (output_control)real-array $\leadsto$ real
The lined up matrices A , C , Q , possibly G and u , and if necessary L stored in row-major order.
- ▷ **Measurement** (output_control)real-array $\leadsto$ real
The matrix R stored in row-major order.
- ▷ **Prediction** (output_control)real-array $\leadsto$ real
The matrix P_0 (error covariance matrix of the initial state estimate) stored in row-major order and the initial state estimate x_0 lined up.

Example

```
* An example of the description-file:
*
* n=3 m=1 p=0
* A+C+Q+G-u-L-R+P+x+
* transition matrix A:
* 1 1 0.5
* 0 1 1
* 0 0 1
* measurement matrix C:
* 1 0 0
* system-error covariance matrix Q:
* 54.3 37.9 48.0
* 37.9 34.3 42.5
* 48.0 42.5 43.7
* measurement-error covariance matrix R:
* 1.2
* estimation-error covariance matrix (for the initial estimate) P0: \
* 0 0 0
* 0 180.5 0
* 0 0 100
* initial estimate x0:
* 0 100 0
*
* the result of read_kalman with the upper descriptionfile
* as inputparameter:
*
* Dimension    = [3,1,0]
* Model        = [1.0,1.0,0.5,0.0,1.0,1.0,0.0,0.0,1.0,1.0,0.0,0.0,
*                  54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]
* Measurement  = [1.2]
* Prediction   = [0.0,0.0,0.0,0.0,0.0,180.5,0.0,0.0,0.0,100.0,0.0,100.0,
*                  0.0].
```

Result

If the description file is readable and correct, the operator `read_kalman` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

[filter_kalman](#)

Module

Foundation

```
select_lines ( : : RowBeginIn, ColBeginIn, RowEndIn, ColEndIn,
               Feature, Operation, Min, Max : RowBeginOut, ColBeginOut,
               RowEndOut, ColEndOut )
```

Select lines according to various criteria.

select_lines is obsolete and is only provided for reasons of backward compatibility.

The operator `select_lines` chooses lines according to various criteria. For every input line the indicated features (**Feature**) are calculated. If each (**Operation** = 'and') or at least one (**Operation** = 'or') of the calculated features is within the given limits (**Min,Max**) the line is transferred into the output. The default values 'min' and 'max' of the parameters **Min** and **Max** are used to leave bottom and top limits, respectively, open.

Condition:

$$Min_i \leq Feature_i(Line) \leq Max_i$$

Possible values for **Feature**:

'length' (Euclidean) length of the line

'row' Line index of the center

'column' Column index of the center

'phi' Orientation of the line ($-\frac{\pi}{2} < \varphi \leq \frac{\pi}{2}$)

Attention

If only one feature is used the value of **Operation** is meaningless. Several features are processed according to the sequence in which they are passed.

Parameters

- ▷ **RowBeginIn** (input_control) line.begin.y-array $\leadsto$ integer
Row coordinates of the starting points of the input lines.
- ▷ **ColBeginIn** (input_control) line.begin.x-array $\leadsto$ integer
Column coordinates of the starting points of the input lines.
- ▷ **RowEndIn** (input_control) line.end.y-array $\leadsto$ integer
Row coordinates of the ending points of the input lines.
- ▷ **ColEndIn** (input_control) line.end.x-array $\leadsto$ integer
Column coordinates of the ending points of the input lines.
- ▷ **Feature** (input_control) string(-array) $\leadsto$ string
Features to be used for selection.
Default: 'length'
List of values: $Feature \in \{\text{'length', 'row', 'column', 'phi'}\}$
- ▷ **Operation** (input_control) string $\leadsto$ string
Desired combination of the features.
Default: 'and'
List of values: $Operation \in \{\text{'and', 'or'}\}$
- ▷ **Min** (input_control) string(-array) $\leadsto$ string / integer / real
Lower limits of the features or 'min'.
Default: 'min'
- ▷ **Max** (input_control) string(-array) $\leadsto$ string / integer / real
Upper limits of the features or 'max'.
Default: 'max'
- ▷ **RowBeginOut** (output_control) line.begin.y-array $\leadsto$ integer
Row coordinates of the starting points of the output lines.
- ▷ **ColBeginOut** (output_control) line.begin.x-array $\leadsto$ integer
Column coordinates of the starting points of the output lines.
- ▷ **RowEndOut** (output_control) line.end.y-array $\leadsto$ integer
Row coordinates of the ending points of the output lines.
- ▷ **ColEndOut** (output_control) line.end.x-array $\leadsto$ integer
Column coordinates of the ending points of the output lines.

Result

The operator `select_lines` returns the value 2 (`H_MSG_TRUE`) if the parameter values are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`sobel_amp`, `edges_image`, `threshold`, `hysteresis_threshold`, `split_skeleton_region`, `split_skeleton_lines`

Possible Successors

`set_line_width`, `disp_line`

Module

Foundation

```
select_lines_longest ( : : RowBeginIn, ColBeginIn, RowEndIn,
                        ColEndIn, Num : RowBeginOut, ColBeginOut, RowEndOut, ColEndOut )
```

Select the longest input lines.

`select_lines_longest` is obsolete and is only provided for reasons of backward compatibility.

The operator `select_lines_longest` selects the `Num` longest input lines from the input lines described by the tuples `RowBeginIn`, `ColBeginIn`, `RowEndIn` and `ColEndIn`.

Parameters

- ▷ **RowBeginIn** (input_control) line.begin.y-array $\leadsto$ *integer*
Row coordinates of the starting points of the input lines.
- ▷ **ColBeginIn** (input_control) line.begin.x-array $\leadsto$ *integer*
Column coordinates of the starting points of the input lines.
- ▷ **RowEndIn** (input_control) line.end.y-array $\leadsto$ *integer*
Row coordinates of the ending points of the input lines.
- ▷ **ColEndIn** (input_control) line.end.x-array $\leadsto$ *integer*
Column coordinates of the ending points of the input lines.
- ▷ **Num** (input_control) integer $\leadsto$ *integer*
(Maximum) desired number of output lines.
Default: 10
- ▷ **RowBeginOut** (output_control) line.begin.y-array $\leadsto$ *integer*
Row coordinates of the starting points of the output lines.
- ▷ **ColBeginOut** (output_control) line.begin.x-array $\leadsto$ *integer*
Column coordinates of the starting points of the output lines.
- ▷ **RowEndOut** (output_control) line.end.y-array $\leadsto$ *integer*
Row coordinates of the ending points of the output lines.
- ▷ **ColEndOut** (output_control) line.end.x-array $\leadsto$ *integer*
Column coordinates of the ending points of the output lines.

Result

The operator `select_lines_longest` returns the value 2 (`H_MSG_TRUE`) if the parameter values are correct. Otherwise an exception is raised.

Module

Foundation

```
update_kalman ( : : FileName, DimensionIn, ModelIn,
                MeasurementIn : DimensionOut, ModelOut, MeasurementOut )
```

Read an update file of a Kalman filter.

update_kalman is obsolete and is only provided for reasons of backward compatibility.

The operator `update_kalman` reads the update file [FileName](#) of a Kalman filter. Kalman filters return an estimate of the current state (or even the prediction of a future state) of a discrete, stochastically disturbed, linear system.

A Kalman filtering is based on a mathematical model of the system to be examined which at any point in time has the following characteristics:

Model parameter: transition matrix A , control matrix G including the controller output u and the measurement matrix C

Model stochastic: system-error covariance matrix Q , system-error - measurement-error covariance matrix L and measurement-error covariance matrix R

Measurement vector: y

History of the system: extrapolation vector $\hat{x}$ and extrapolation-error covariance matrix $\hat{P}$

Many systems do not need entries “from outside” and therefore G and u can be dropped. Further, system errors and measurement errors are normally not correlated (L is dropped). Some of the characteristics mentioned above may change dynamically (from one iteration to the next). The operator `update_kalman` serves to modify parts of the system according to an update file (ASCII) with the following structure (see also [read_kalman](#)):

Dimension row

```
+ content row
+ matrix A
+ matrix C
+ matrix Q
+ matrix G + vector u
+ matrix L
+ matrix R
```

The dimension row thereby has the following form:

$$n = \langle \text{integer} \rangle \quad m = \langle \text{integer} \rangle \quad p = \langle \text{integer} \rangle$$

whereby n indicates the number of the state variables, m the number of the measurement values and p the number of the controller members (see also [DimensionIn](#) / [DimensionOut](#)). The maximal dimension will hereby be limited by a system constant (= 30 for the time being). As in this case changes should take effect at a valid model, the dimensions n and m are invariant (and will only be indicated for purposes of control).

The content row has the following form:

$$A * C * Q * G * u * L * R *$$

and describes the further content of the file. Instead of '*', '+' (= parameter is available) respectively '-' (= parameter is missing) has to be set. In contrast to description files for `read_kalman`, the system description needs not be complete in this case. Only those parts of the system which are changed must be indicated. The indication of estimated values is unnecessary, as these values must stem from the latest filtering according to the structure of the filter.

$(r \times s)$ matrices will be stored in row-major order in the following form:

$$\begin{array}{cccc} & & < \text{comment, i.e. string} > & \\ < a_{11} > & < a_{12} > & \cdots & < a_{1s} > \\ & \vdots & & & \ddots & \\ < a_{r1} > & < a_{r2} > & \cdots & < a_{rs} > \end{array}$$

(the spaces/line feed characters can be chosen at will),

vectors will be stored correspondingly in the following form:

$$\begin{array}{ccc} & < \text{comment, i.e. string} > \\ < a_1 > & \cdots & < a_k > \end{array}$$

The following parameter values of the operator `read_kalman` will be changed:

DimensionIn / DimensionOut: These parameters include the dimensions of the state vector, measurement vector and controller vector and therefore are vectors $[n, m, p]$, whereby 'n' indicates the number of the state variables, 'm' the number of the measurement values and 'p' the number of the controller members. 'n' and 'm' are invariant for a given system, i.e. they must not differ from corresponding input values of the update file. For a system without influence "from outside" $p = 0$.

ModelIn / ModelOut: These parameters include the lined up matrices (vectors) 'A, C, Q, G, u' and if necessary 'L' which have been stored in row-major order. `ModelIn / ModelOut` therefore are vectors of the length $n \times n + n \times m + n \times n + n \times p + p[+n \times m]$. The last summand is dropped if system errors and measurement errors are not correlated, i.e. no value has been set for 'L'.

MeasurementIn / MeasurementOut: These parameters include the matrix 'R' stored in row-major order, and therefore are vectors of the dimension $m \times m$.

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ string
Update file for a Kalman filter.
Default: 'kalman.updt'
- ▷ **DimensionIn** (input_control) integer-array $\leadsto$ integer
The dimensions of the state vector, measurement vector and controller vector.
Default: [3,1,0]
Value range: $0 \leq \text{DimensionIn} \leq 30$
- ▷ **ModelIn** (input_control) real-array $\leadsto$ real
The lined up matrices A,C,Q, possibly G and u, and if necessary L which all have been stored in row-major order.
Default: [1.0,1.0,0.5,0.0,1.0,1.0,0.0,0.0,1.0,1.0,0.0,0.0,54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]
Value range: $0.0 \leq \text{ModelIn} \leq 10000.0$
- ▷ **MeasurementIn** (input_control) real-array $\leadsto$ real
The matrix R stored in row-major order.
Default: [1,2]
Value range: $0.0 \leq \text{MeasurementIn} \leq 10000.0$
- ▷ **DimensionOut** (output_control) integer-array $\leadsto$ integer
The dimensions of the state vector, measurement vector and controller vector.
- ▷ **ModelOut** (output_control) real-array $\leadsto$ real
The lined up matrices A,C,Q, possibly G and u, and if necessary L which all have been stored in row-major order.
- ▷ **MeasurementOut** (output_control) real-array $\leadsto$ real
The matrix R stored in row-major order.

Example

```

* The following values are describing the system
*
* DimensionIn      = [3,1,0]
* ModelIn          = [1.0,1.0,0.5,0.0,1.0,1.0,0.0,0.0,1.0,1.0,0.0,0.0,
*                    54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]
* MeasurementIn = [1,2]
*
* An example of the Updatefile:
*
* n=3 m=1 p=0
* A+C-Q-G-u-L-R-
* transitions at time t=15:
* 2 1 1
* 0 2 2
* 0 0 2
*
* the results of update_kalman:
*
* DimensionOut     = [3,1,0]
* ModelOut         = [2.0,1.0,1.0,0.0,2.0,2.0,0.0,0.0,2.0,1.0,0.0,0.0,
*                    54.3,37.9,48.0,37.9,34.3,42.5,48.0,42.5,43.7]
* MeasurementOut = [1.2]

```

Result

If the update file is readable and correct, the operator `update_kalman` returns the value 2 (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

17.15 XLD

```

union_straight_contours_histo_xld ( Contours : UnionContours,
    SelectedContours : RefLineStartRow, RefLineStartColumn,
    RefLineEndRow, RefLineEndColumn, Width, MaxWidth,
    FilterSize : HistoValues )

```

Compute the union of neighboring straight contours that have a similar distance from a given line.

`union_straight_contours_histo_xld` is obsolete and is only provided for reasons of backward compatibility. New applications should use the operators of the chapter 1D Measuring instead.

`union_straight_contours_histo_xld` merges neighboring XLD contours [Contours](#) if certain criteria are fulfilled.

The maximum and minimum distances of the contours to a given reference line are calculated. From this distances a histogram is created. If the histogram should be smoothed, [FilterSize](#) must be greater than one. Afterwards,

the resulting histogram is divided into ranges (from minima to minima). Contours which lie in the same range are concatenated to a new contour. If the width of the range is greater than `MaxWidth`, all contours in this range are ignored (removed). If a contour lies in two ranges or more it is ignored, too. If there are parallel contours, there is a risk of merging neighboring contours.

The parameters of the regression lines are calculated newly for merged contours.

The resulting contours cannot be displayed.

Attention

Before the contour parameters can be returned by `union_straight_contours_histo_xld`, the parameters of the regression line to the contour must be calculated by calling `regress_contours_xld`. Note further that already closed contours are not considered for a union anymore.

Parameters

- ▷ **Contours** (input_object) xld_cont-array $\leadsto$ object
Input XLD contours.
- ▷ **UnionContours** (output_object) xld_cont-array $\leadsto$ object
Output XLD contours.
- ▷ **SelectedContours** (output_object) xld_cont-array $\leadsto$ object
Output XLD contours.
- ▷ **RefLineStartRow** (input_control) line.begin.y $\leadsto$ integer
y coordinate of the starting point of the reference line.
Default: 0
- ▷ **RefLineStartColumn** (input_control) line.begin.x $\leadsto$ integer
x coordinate of the starting point of the reference line.
Default: 0
- ▷ **RefLineEndRow** (input_control) line.end.y $\leadsto$ integer
y coordinate of the endpoint of the reference line.
Default: 0
- ▷ **RefLineEndColumn** (input_control) line.end.x $\leadsto$ integer
x coordinate of the endpoint of the reference line.
Default: 0
- ▷ **Width** (input_control) integer $\leadsto$ integer
Maximum distance.
Default: 1
- ▷ **MaxWidth** (input_control) integer $\leadsto$ integer
Maximum width between two minima.
Default: 1
- ▷ **FilterSize** (input_control) integer $\leadsto$ integer
Size of smoothing filter
Default: 1
Value range: $1 \leq \text{FilterSize} \leq 63$
- ▷ **HistoValues** (output_control) integer-array $\leadsto$ integer
Output values of histogram.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Chapter 18

Matching

18.1 Component-Based

clear_component_model (: : ComponentModelID :)

Free the memory of a component model.

The operator `clear_component_model` frees the memory of a component model that was created by `create_component_model` or `create_trained_component_model`. After calling `clear_component_model`, the model can no longer be used. The handle `ComponentModelID` becomes invalid.

Parameters

- ▷ **ComponentModelID** (input_control) component_model $\leadsto$ handle
Handle of the component model.

Result

If the handle of the model is valid, the operator `clear_component_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ComponentModelID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_component_model`, `create_trained_component_model`, `read_component_model`, `write_component_model`

Module

Matching

clear_training_components (: : ComponentTrainingID :)

Free the memory of a component training result.

The operator `clear_training_components` frees the memory of a training result that was created by `train_model_components`. After calling `clear_training_components`, the training result can no longer be used. The handle `ComponentTrainingID` becomes invalid.

Parameters

- ▷ **ComponentTrainingID** (input_control) component_training $\leadsto$ handle
Handle of the training result.

Result

If the handle of the training result is valid, the operator `clear_training_components` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ComponentTrainingID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`train_model_components`, `write_training_components`

Module

Matching

```
cluster_model_components (
    TrainingImages : ModelComponents : ComponentTrainingID,
    AmbiguityCriterion, MaxContourOverlap, ClusterThreshold : )
```

Adopt new parameters that are used to create the model components into the training result.

With `cluster_model_components` you can modify parameters *after* a first training has been performed using `train_model_components`. `cluster_model_components` sets the criterion `AmbiguityCriterion` that is used to solve the ambiguities, the maximum contour overlap `MaxContourOverlap`, and the cluster threshold of the training result `ComponentTrainingID` to the specified values. A detailed description of these parameters can be found in the documentation of `train_model_components`. By modifying these parameters, the way in which the initial components are merged into rigid model components changes. For example, the greater the cluster threshold is chosen, the fewer initial components are merged. You can select suitable parameter values interactively by repeatedly calling `inspect_clustered_components` with different parameter values and then setting the chosen values by using `get_training_components`.

The rigid model components are returned in `ModelComponents`. In order to receive reasonable results, it is essential that the same training images that were used to perform the training with `train_model_components` are passed in `TrainingImages`. The pose of the newly clustered components within the training images is determined using the shape-based matching. As in `train_model_components`, one can decide whether the shape models should be pregenerated by using `set_system('pregenerate_shape_models', ...)`. Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. `set_system('border_shape_models', ...)` can be used to determine whether the models must lie completely within the training images or whether they can extend partially beyond the image border.

Parameters

- ▷ **TrainingImages** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / uint2
Training images that were used for training the model components.
- ▷ **ModelComponents** (output_object) region(-array) $\leadsto$ *object*
Contour regions of rigid model components.
- ▷ **ComponentTrainingID** (input_control) component_training $\leadsto$ *handle*
Handle of the training result.
- ▷ **AmbiguityCriterion** (input_control) string $\leadsto$ *string*
Criterion for solving the ambiguities.
Default: 'rigidity'
List of values: AmbiguityCriterion $\in$ {'distance', 'orientation', 'distance_orientation', 'rigidity'}
- ▷ **MaxContourOverlap** (input_control) real $\leadsto$ *real*
Maximum contour overlap of the found initial components.
Default: 0.2
Suggested values: MaxContourOverlap $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: 0 <= MaxContourOverlap && MaxContourOverlap <= 1
- ▷ **ClusterThreshold** (input_control) real $\leadsto$ *real*
Threshold for clustering the initial components.
Default: 0.5
Suggested values: ClusterThreshold $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: 0 <= ClusterThreshold && ClusterThreshold <= 1

Example

```
* Get the model image.
read_image (ModelImage, 'model_image.tif')
* Define the regions for the initial components.
gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
* Get the training images
gen_empty_obj (TrainingImages)
for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-'+i$'02'+'.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
endfor
* Extract the model components and train the relations.
train_model_components (ModelImage, InitialComponentRegions, \
    TrainingImages, ModelComponents, 22, 60, 30, 0.65, \
    0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.5, \
    ComponentTrainingID)
* Find the best value for the parameter ClusterThreshold.
inspect_clustered_components (ModelComponents, ComponentTrainingID, \
    'rigidity', 0.2, 0.4)
* Adopt the ClusterThreshold into the training result.
cluster_model_components (TrainingImages, ModelComponents, \
    ComponentTrainingID, 'rigidity', 0.2, 0.4)
* Create the component model based on the training result.
create_trained_component_model (ComponentTrainingID, -rad(30), rad(60), \
    10, 0.5, 'auto', 'auto', 'none', \
    'use_polarity', 'false', ComponentModelID, \
    RootRanking)
```

Result

If the parameter values are correct, the operator `cluster_model_components` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`train_model_components`, `inspect_clustered_components`

Possible Successors

`get_training_components`, `create_trained_component_model`,
`modify_component_relations`, `write_training_components`,
`get_component_relations`, `clear_training_components`

Module

Matching

```
create_component_model ( ModelImage,
    ComponentRegions : : VariationRow, VariationColumn,
    VariationAngle, AngleStart, AngleExtent, ContrastLowComp,
    ContrastHighComp, MinSizeComp, MinContrastComp, MinScoreComp,
    NumLevelsComp, AngleStepComp, OptimizationComp, MetricComp,
    PregenerationComp : ComponentModelID, RootRanking )
```

Prepare a component model for matching based on explicitly specified components and relations.

`create_component_model` prepares patterns, which are passed in the form of a model image `ModelImage` and several regions `ComponentRegions`, as a component model for matching. The output parameter `ComponentModelID` is a handle for this model, which is used in subsequent calls to `find_component_model`. In contrast to `create_trained_component_model`, no preceding training with `train_model_components` needs to be performed before calling `create_component_model`.

Each of the regions passed in `ComponentRegions` describes a separate model component. Later, the index of a component region in `ComponentRegions` is used to denote the model component. The reference point of a component is the center of gravity of its associated region, which is passed in `ComponentRegions`. It can be calculated by calling `area_center`.

The relative movements (relations) of the model components can be set by passing `VariationRow`, `VariationColumn`, and `VariationAngle`. Because directly passing the relations is complicated, instead of the relations the variations of the model components are passed. The variations describe the movements of the components independently from each other relative to their poses in the model image `ModelImage`. The parameters `VariationRow` and `VariationColumn` describe the movement of the components in row and column direction by $\pm \frac{1}{2} \text{VariationRow}$ and $\pm \frac{1}{2} \text{VariationColumn}$, respectively. The parameter `VariationAngle` describes the angle variation of the component by $\pm \frac{1}{2} \text{VariationAngle}$. Based on these values, the relations are automatically computed. The three parameters must either contain one element, in which case the parameter is used for all model components, or must contain the same number of elements as `ComponentRegions`, in which case each parameter element refers to the corresponding model component in `ComponentRegions`.

The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations of the component model in an image.

Internally, a separate shape model is built for each model component (see `create_shape_model`). Therefore, the parameters `ContrastLowComp`, `ContrastHighComp`, `MinSizeComp`, `MinContrastComp`, `MinScoreComp`, `NumLevelsComp`, `AngleStepComp`, `OptimizationComp`, `MetricComp`, and `PregenerationComp` correspond to the parameters of `create_shape_model`, with the following differences: First, in the parameter `Contrast` of `create_shape_model` the upper as well as the lower threshold for the hysteresis threshold method can be passed. Additionally, a third value, which suppresses small connected

contour regions, can be passed. In contrast, the operator `create_component_model` offers three separate parameters `ContrastHighComp`, `ContrastLowComp`, and `MinScoreComp` in order to set these three values. Consequently, also the automatic computation of the contrast threshold(s) is different. If both hysteresis threshold should be automatically determined, both `ContrastLowComp` and `ContrastHighComp` must be set to `'auto'`. In contrast, if only one threshold value should be determined, `ContrastLowComp` must be set to `'auto'` while `ContrastHighComp` must be set to an arbitrary value different from `'auto'`. Secondly, the parameter `Optimization` of `create_shape_model` provides the possibility to reduce the number of model points as well as the possibility to completely pregenerate the shape model. In contrast, the operator `create_trained_component_model` uses a separate parameter `PregenerationComp` in order to decide whether the shape models should be completely pregenerated or not. A third difference concerning the parameter `MinScoreComp` should be noted. When using the shape-based matching, this parameter needs not be passed when preparing the shape model using `create_shape_model`, but only during the search using `find_shape_model`. In contrast, when preparing the component model it is favorable to analyze rotational symmetries of the model components and similarities between the model components. However, this analysis only leads to meaningful results if the value for `MinScoreComp` that is used during the search (see `find_component_model`) is already approximately known.

In addition to the parameters `ContrastLowComp`, `ContrastHighComp`, and `MinSizeComp` also the parameters `MinContrastComp`, `NumLevelsComp`, `AngleStepComp`, and `OptimizationComp` can be automatically determined by passing `'auto'` for the respective parameters.

All component-specific input parameters (parameter names terminate with the suffix `Comp`) must either contain one element, in which case the parameter is used for all model components, or must contain the same number of elements as the number of regions in `ComponentRegions`, in which case each parameter element refers to the corresponding element in `ComponentRegions`.

In addition to the individual shape models, the component model also contains information about the way the single model components must be searched relative to each other using `find_component_model` in order to minimize the computation time of the search. For this, the components are represented in a tree structure. First, the component that stands at the root of this search tree (root component) is searched. Then, the remaining components are searched relative to the pose of their predecessor in the search tree.

The root component can be passed as an input parameter of `find_component_model` during the search. To what extent a model component is suited to act as the root component depends on several factors. In principle, a model component that can be found in the image with a high probability should be chosen. Therefore, a component that is sometimes occluded to a high degree or that is missing in some cases is not well suited to act as the root component. Additionally, the computation time that is associated with the root component during the search can serve as a criterion. A ranking of the model components that is based on the latter criterion is returned in `RootRanking`. In this parameter the indices of the model components are sorted in descending order according to their associated search time, i.e., `RootRanking[0]` contains the index of the model component that, chosen as root component, allows the fastest search. Note that the ranking returned in `RootRanking` represents only a coarse estimation. Furthermore, the calculation of the root ranking assumes that the image size as well as the value of the system parameter `'border_shape_models'` are identical when calling `create_component_model` and `find_component_model`.

Parameters

- ▷ **ModelImage** (input_object) (multichannel-)image $\leadsto$ *object* : byte / uint2
Input image from which the shape models of the model components should be created.
- ▷ **ComponentRegions** (input_object) region-array $\leadsto$ *object*
Input regions from which the shape models of the model components should be created.
- ▷ **VariationRow** (input_control) integer(-array) $\leadsto$ *integer*
Variation of the model components in row direction.
Suggested values: `VariationRow` $\in$ {0, 1, 2, 3, 4, 5, 10, 20, 30, 40, 50, 100, 150}
Restriction: `VariationRow` $\geq$ 0
- ▷ **VariationColumn** (input_control) integer(-array) $\leadsto$ *integer*
Variation of the model components in column direction.
Suggested values: `VariationColumn` $\in$ {0, 1, 2, 3, 4, 5, 10, 20, 30, 40, 50, 100, 150}
Restriction: `VariationColumn` $\geq$ 0
- ▷ **VariationAngle** (input_control) angle.rad(-array) $\leadsto$ *real*
Angle variation of the model components.
Suggested values: `VariationAngle` $\in$ {0.0, 0.017, 0.035, 0.05, 0.07, 0.09, 0.17, 0.35, 0.52, 0.67, 0.87}
Restriction: `VariationAngle` $\geq$ 0

- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the component model.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation of the component model.
Default: 0.79
Suggested values: AngleExtent $\in$ {6.28, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtent ≥ 0
- ▷ **ContrastLowComp** (input_control) integer(-array) $\leadsto$ integer / string
Lower hysteresis threshold for the contrast of the components in the model image.
Default: 'auto'
Suggested values: ContrastLowComp $\in$ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
Restriction: ContrastLowComp > 0
- ▷ **ContrastHighComp** (input_control) integer(-array) $\leadsto$ integer / string
Upper hysteresis threshold for the contrast of the components in the model image.
Default: 'auto'
Suggested values: ContrastHighComp $\in$ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
Restriction: ContrastHighComp > 0 && ContrastHighComp $\geq$ ContrastLowComp
- ▷ **MinSizeComp** (input_control) integer(-array) $\leadsto$ integer / string
Minimum size of the contour regions in the model.
Default: 'auto'
Suggested values: MinSizeComp $\in$ {'auto', 0, 5, 10, 20, 30, 40}
Restriction: MinSizeComp ≥ 0
- ▷ **MinContrastComp** (input_control) integer(-array) $\leadsto$ integer / string
Minimum contrast of the components in the search images.
Default: 'auto'
Suggested values: MinContrastComp $\in$ {'auto', 10, 20, 20, 40}
Restriction: MinContrastComp $\leq$ ContrastLowComp && MinContrastComp ≥ 0
- ▷ **MinScoreComp** (input_control) real(-array) $\leadsto$ real
Minimum score of the instances of the components to be found.
Default: 0.5
Suggested values: MinScoreComp $\in$ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: $0 \leq$ MinScoreComp && MinScoreComp ≤ 1
- ▷ **NumLevelsComp** (input_control) integer(-array) $\leadsto$ integer / string
Maximum number of pyramid levels for the components.
Default: 'auto'
List of values: NumLevelsComp $\in$ {'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStepComp** (input_control) angle.rad(-array) $\leadsto$ real / string
Step length of the angles (resolution) for the components.
Default: 'auto'
Suggested values: AngleStepComp $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStepComp ≥ 0
- ▷ **OptimizationComp** (input_control) string $\leadsto$ string
Kind of optimization for the components.
Default: 'auto'
List of values: OptimizationComp $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}
- ▷ **MetricComp** (input_control) string(-array) $\leadsto$ string
Match metric used for the components.
Default: 'use_polarity'
List of values: MetricComp $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}

- ▷ **PregenerationComp** (input_control)string(-array) $\leadsto$ *string*
Complete pregeneration of the shape models for the components if equal to 'true'.
Default: 'false'
List of values: PregenerationComp $\in$ {'true', 'false'}
- ▷ **ComponentModelID** (output_control) component_model $\leadsto$ *handle*
Handle of the component model.
- ▷ **RootRanking** (output_control) integer(-array) $\leadsto$ *integer*
Ranking of the model components expressing the suitability to act as the root component.

Example

```
* Read the model image.
read_image (ModelImage, 'model_image.tif')
* Describe the model components.
gen_rectangle2 (ComponentRegions, 318, 109, -1.62, 34, 19)
gen_rectangle2 (Rectangle2, 342, 238, -1.63, 32, 17)
gen_rectangle2 (Rectangle3, 355, 505, 1.41, 25, 17)
concat_obj (ComponentRegions, Rectangle2, ComponentRegions)
concat_obj (ComponentRegions, Rectangle3, ComponentRegions)
* Create the component model by explicitly specifying the relations.
create_component_model (ModelImage, ComponentRegions, 20, 20, rad(25), 0, \
    rad(360), 15, 40, 15, 10, 0.8, 'auto', 'auto', \
    'none', 'use_polarity', 'false', ComponentModelID, \
    RootRanking)
* Find the component model in a run-time image.
read_image (SearchImage, 'search_image.tif')
find_component_model (SearchImage, ComponentModelID, RootRanking, 0, \
    rad(360), 0.5, 0, 0.5, 'stop_search', \
    'search_from_best', 'none', 0.8, 'least_squares', 0, \
    0.8, ModelStart, ModelEnd, Score, RowComp, \
    ColumnComp, AngleComp, ScoreComp, ModelComp)
```

Result

If the parameters are valid, the operator `create_component_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`draw_region, concat_obj`

Possible Successors

`find_component_model`

Alternatives

`create_trained_component_model`

Module

Matching

```
create_trained_component_model ( : : ComponentTrainingID,
    AngleStart, AngleExtent, MinContrastComp, MinScoreComp,
    NumLevelsComp, AngleStepComp, OptimizationComp, MetricComp,
    PregenerationComp : ComponentModelID, RootRanking )
```

Prepare a component model for matching based on trained components.

`create_trained_component_model` prepares the training result, which is passed in `ComponentTrainingID`, as a component model for matching. The output parameter `ComponentModelID` is a handle for this model, which is used in subsequent calls to `find_component_model`. In contrast to `create_component_model`, the model components must have been previously trained using `train_model_components` before calling `create_trained_component_model`.

The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations of the component model in an image.

Internally, a separate shape model is built for each model component (see `create_shape_model`). Therefore, the parameters `MinContrastComp`, `MinScoreComp`, `NumLevelsComp`, `AngleStepComp`, `OptimizationComp`, `MetricComp`, and `PregenerationComp` correspond to the parameters of `create_shape_model`, with the following differences: First, the parameter `OptimizationComp` of `create_shape_model` provides the possibility to reduce the number of model points as well as the possibility to completely pregenerate the shape model. In contrast, the operator `create_trained_component_model` uses a separate parameter `PregenerationComp` in order to decide whether the shape models should be completely pregenerated or not. A second difference concerning the parameter `MinScoreComp` should be noted. When using the shape-based matching, this parameter needs not be passed when preparing the shape model using `create_shape_model` but only during the search using `find_shape_model`. In contrast, when preparing the component model it is favorable to analyze rotational symmetries of the model components and similarities between the model components. However, this analysis only leads to meaningful results if the value for `MinScoreComp` that is used during the search (see `find_component_model`) is already approximately known. After the search with `find_component_model` the pose parameters of the components in a search image are returned. Note that the pose parameters refer to the reference points of the components. The reference point of a component is the center of gravity of its associated region that is returned in `ModelComponents` of `train_model_components`.

The parameters `MinContrastComp`, `NumLevelsComp`, `AngleStepComp`, and `OptimizationComp` can be automatically determined by passing 'auto' for the respective parameters.

All component-specific input parameters (parameter names terminate with the suffix `Comp`) must either contain one element, in which case the parameter is used for all model components, or must contain the same number of elements as the number of model components contained in `ComponentTrainingID`, in which case each parameter element refers to the corresponding component in `ComponentTrainingID`.

In addition to the individual shape models, the component model also contains information about the way the single model components must be searched relative to each other using `find_component_model` in order to minimize the computation time of the search. For this, the components are represented in a tree structure. First, the component that stands at the root of this search tree (root component) is searched. Then, the remaining components are searched relative to the pose of their predecessor in the search tree.

The root component can be passed as an input parameter of `find_component_model` during the search. To what extent a model component is suited to act as root component depends on several factors. In principle, a model component that can be found in the image with a high probability should be chosen. Therefore, a component that is sometimes occluded to a high degree or that is missing in some cases is not well suited to act as root component. Additionally, the computation time that is associated with the root component during the search can serve as a criterion. A ranking of the model components that is based on the latter criterion is returned in `RootRanking`. In this parameter the indices of the model components are sorted in descending order according to their associated computation time, i.e., `RootRanking[0]` contains the index of the model component that, chosen as root component, allows the fastest search. Note that the ranking returned in `RootRanking` represents only a coarse estimation. Furthermore, the calculation of the root ranking assumes that the image size as well as the value of the system parameter 'border_shape_models' are identical when calling `create_trained_component_model` and `find_component_model`.

Parameters

- ▷ **ComponentTrainingID** (input_control) component_training ~ handle
Handle of the training result.

- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the component model.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation of the component model.
Default: 0.79
Suggested values: AngleExtent $\in$ {6.28, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtent $\geq$ 0
- ▷ **MinContrastComp** (input_control) integer(-array) $\leadsto$ integer / string
Minimum contrast of the components in the search images.
Default: 'auto'
Suggested values: MinContrastComp $\in$ {'auto', 10, 20, 20, 40}
Restriction: MinContrastComp $\geq$ 0
- ▷ **MinScoreComp** (input_control) real(-array) $\leadsto$ real
Minimum score of the instances of the components to be found.
Default: 0.5
Suggested values: MinScoreComp $\in$ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: 0 $\leq$ MinScoreComp && MinScoreComp $\leq$ 1
- ▷ **NumLevelsComp** (input_control) integer(-array) $\leadsto$ integer / string
Maximum number of pyramid levels for the components.
Default: 'auto'
List of values: NumLevelsComp $\in$ {'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStepComp** (input_control) angle.rad(-array) $\leadsto$ real / string
Step length of the angles (resolution) for the components.
Default: 'auto'
Suggested values: AngleStepComp $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStepComp $\geq$ 0
- ▷ **OptimizationComp** (input_control) string $\leadsto$ string
Kind of optimization for the components.
Default: 'auto'
List of values: OptimizationComp $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}
- ▷ **MetricComp** (input_control) string(-array) $\leadsto$ string
Match metric used for the components.
Default: 'use_polarity'
List of values: MetricComp $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **PregenerationComp** (input_control) string(-array) $\leadsto$ string
Complete pregeneration of the shape models for the components if equal to 'true'.
Default: 'false'
List of values: PregenerationComp $\in$ {'true', 'false'}
- ▷ **ComponentModelID** (output_control) component_model $\leadsto$ handle
Handle of the component model.
- ▷ **RootRanking** (output_control) integer(-array) $\leadsto$ integer
Ranking of the model components expressing the suitability to act as the root component.

Example

```
* Get the model image.
read_image (ModelImage, 'model_image.tif')
* Define the regions for the initial components.
gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
```

```

concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
* Get the training images.
gen_empty_obj (TrainingImages)
for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-'+i+'.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
endfor
* Extract the model components and train the relations.
train_model_components (ModelImage, InitialComponentRegions, \
    TrainingImages, ModelComponents, 22, 60, 30, 0.65, \
    0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.4, \
    ComponentTrainingID)
* Create the component model based on the training result.
create_trained_component_model (ComponentTrainingID, -rad(30), rad(60), 10, \
    0.5, 'auto', 'auto', 'none', \
    'use_polarity', 'false', ComponentModelID, \
    RootRanking)
* Find the component model in a run-time image.
read_image (SearchImage, 'search_image.tif')
find_component_model (SearchImage, ComponentModelID, RootRanking, -rad(30), \
    rad(60), 0.5, 0, 0.5, 'stop_search', 'prune_branch', \
    'none', 0.55, 'least_squares', 0, 0.9, ModelStart, \
    ModelEnd, Score, RowComp, ColumnComp, AngleComp, \
    ScoreComp, ModelComp)

```

Result

If the parameters are valid, the operator `create_trained_component_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

deserialize_component_model (: : SerializedItemHandle : ComponentModelID)

Deserialize a serialized component model.

`deserialize_component_model` deserializes a component model, that was serialized by [serialize_component_model](#) (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The serialized component model is defined by the handle [SerializedItemHandle](#).

The deserialized values are stored in an automatically created component model with the handle `SerializedItemHandle`.

Parameters

- ▷ **SerializedItemHandle** (input_control) serialized_item $\leadsto$ *handle*
Handle of the serialized item.
- ▷ **ComponentModelID** (output_control) component_model $\leadsto$ *handle*
Handle of the component model.

Result

If the parameters are valid, the operator `deserialize_component_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
deserialize_training_components (
    :   : SerializedItemHandle : ComponentTrainingID )
```

Deserialize a component training result.

`deserialize_training_components` deserializes a component training result, that was serialized by `serialize_training_components` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized component training result is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created component training result with the handle `ComponentTrainingID`.

Parameters

- ▷ **SerializedItemHandle** (input_control) serialized_item $\leadsto$ *handle*
Handle of the serialized item.
- ▷ **ComponentTrainingID** (output_control) component_training $\leadsto$ *handle*
Handle of the training result.

Result

If the parameters are valid, the operator `deserialize_training_components` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Matching

```
find_component_model ( Image : : ComponentModelID, RootComponent,
    AngleStartRoot, AngleExtentRoot, MinScore, NumMatches, MaxOverlap,
    IfRootNotFound, IfComponentNotFound, PosePrediction, MinScoreComp,
    SubPixelComp, NumLevelsComp, GreedinessComp : ModelStart,
    ModelEnd, Score, RowComp, ColumnComp, AngleComp, ScoreComp,
    ModelComp )
```

Find the best matches of a component model in an image.

The operator `find_component_model` finds the best `NumMatches` instances of the component model `ComponentModelID` in the input image `Image`.

The result of the search can be visualized using `get_found_component_model`. Also the operator can be used to extract the component matches of a certain component model instance.

Further information about input parameters

ComponentModelID: Handle of the component model.

The model must have been created previously by calling `create_trained_component_model` or `create_component_model`, or read in using `read_component_model`.

RootComponent: Index of the root component.

The components of the component model `ComponentModelID` are represented in a tree structure. The component that stands at the root of this search tree is the root component.

The root component is searched within the full search space, i.e., at all allowed positions and in the allowed range of orientations (see below). In contrast, the remaining components are searched relative to the pose of their predecessor in the search tree within a restricted search space that is computed from the relations (recursive search).

To what extent a model component is suited to act as root component depends on several factors. In principle, a model component that can be found in the image with a high probability, should be chosen. Therefore, a component that is sometimes occluded to a high degree or that is missing in some cases is not well suited to act as root component. For the behavior in such cases, see the entry `IfRootNotFound` below.

A different possible criterion is the computation time that is associated with the root component during the search. A ranking of the model components that is based on the latter criterion is returned in `RootRanking` of the operator `create_trained_component_model` or `create_component_model`, respectively. If the complete ranking is passed in `RootComponent`, the first value `RootComponent[0]` is automatically selected as the root component.

AngleStartRoot and AngleExtentRoot: Specify the allowed angle range (in [rad]) within which the root component is searched.

If necessary, the range of rotations is clipped to the range given when the component model was created with `create_trained_component_model` or `create_component_model`, respectively. The angle range for each component can be queried with `get_shape_model_params`. The necessary handle of the corresponding shape model can be obtained using `get_component_model_params`.

MinScore: Determines what score a potential match of the component model must at least have to be regarded as an instance.

If the component model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9. The value of this parameter only slightly influences the computation time. An exception is the case of `IfRootNotFound` set to `'select_new_root'` (see below).

NumMatches: Determines the maximum number of returned instances.

If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. In case more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. However, if all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

MaxOverlap: Determines by what fraction two instances may at most overlap, whereby this fraction is a number between 0 and 1.

In some cases, found instances only differ in the pose of one or a few components. If two instances overlap each other by more than **MaxOverlap** only the best instance is returned. This means, for **MaxOverlap** = 0, the found instances may not overlap at all, while for **MaxOverlap** = 1 no check for overlap is performed, and hence all instances are returned. The calculation of the overlap is based on the smallest enclosing rectangles of arbitrary orientation (see **smallest_rectangle2**) of the found component instances.

IfRootNotFound: specifies the behavior of the operator when dealing with a missing or strongly occluded root component.

Possible values:

- **'stop_search'**: It is assumed that the root component is always found in the image. Consequently, for instances for which the root component could not be found the search for the remaining components is not continued.
- **'select_new_root'**: Different components are successively chosen as the root component and searched within the full search space. The order in which the selection of the root component is performed corresponds to the order passed in **RootRanking**. The poses of the found instances of all root components are then used to start the recursive search for the remaining components. Hence, it is possible to find instances even if the original root component is not found. However, the computation time of the search increases significantly in comparison to the search when choosing **'stop_search'**. This is especially the case for small values of **MinScore**, as more root components must be searched. If during the search more root components are needed as given in **RootComponent**, the root components are completed by the automatically computed order (see **create_trained_component_model** or **create_component_model**).

IfComponentNotFound: Specifies how components are searched when the predecessor component was not found (e.g., because she is missing or strongly occluded).

Possible values:

- **'prune_branch'**: Such components are not searched at all and are also treated as 'not found'.
- **'search_from_upper'**: Such components are searched relative to the pose of the predecessor component of the predecessor component.
- **'search_from_best'**: Such components are searched relative to the pose of the already found component from which the relative search can be performed with minimum computational effort.

PosePrediction: Determines whether the pose of not found components should be estimated.

Possible values:

- **'none'**: Only the poses of the found components are returned.
- **'from_neighbors'**: The poses of not found components are estimated and returned with a score of **ScoreComp** = 0.0. The pose estimation is based on the poses of the found neighboring components in the search tree.
- **'from_all'**: The poses of not found components are estimated and returned with a score of **ScoreComp** = 0.0. The pose estimation is based on the poses of all found components.

MinScoreComp: Minimal necessary score of the components for the instances to be found.

This parameter has the same meaning as **MinScore** in **find_shape_model**.

Settable is either one element or the same number of elements as model components in **ComponentModelID**. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in **ComponentModelID**.

SubPixelComp: Determines whether the extraction shall be done subpixel precise and in the given case the maximal allowed object deformation in pixels.

This parameter has the same meaning as **SubPixel** in **find_shape_model**. Therefore the maximal allowed object deformation has to be given as integer in the same string. Settable is either one element or the same number of elements as model components in **ComponentModelID**. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in **ComponentModelID**.

Example: **['least_squares', 'max_deformation 2']**.

NumLevelsComp: Determine the pyramid levels for the components used in the matching.

This parameter has the same meaning as **NumLevels** in **find_shape_model**.

It determines the number of pyramid levels for the components to be used in the matching. Settable is either one element or the same number of elements as model components in `ComponentModelID`. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in `ComponentModelID`.

Optional, one can set value pairs for this parameter: In this case, the first value still determines the number of pyramid levels to be used. The second value specifies the lowest pyramid level, to which the found matches are tracked. In doing so, one can set either a single value pair or a value pair for each model component in `ComponentModelID`. If different value pairs should be used for different components, they must be specified in the same tuple. In case `ComponentModelID` contains exactly two components and in `NumLevelsComp` two values are set, these values are interpreted as different number of pyramid levels to be used and not as a value pair.

Example: `ComponentModelID` contains two components, for which different pyramid levels shall be considered. For the first component 5 levels up to the level 2 shall be used. For the second component 4 levels up to the level 1 shall be used. In this case is `NumLevelsComp` = [5,2,4,1].

GreedinessComp: “Greediness” of the search heuristic for the components: value from 0 to 1. Thereby 0 means: safe but slow, 1: fast but matches may be missed.

This parameter has the same meaning as Greediness in `find_shape_model`.

Settable is either one element or the same number of elements as model components in `ComponentModelID`. In the first case the parameter is used for all components. In the second case, each parameter element refers to the corresponding component in `ComponentModelID`.

Further information about output parameters

ModelStart and ModelEnd: Return the first and last index and therewith the index range of all component matches associated to the same instance of the component model.

The component matches corresponding to the first found instance of the component model are given by the interval of indices [`ModelStart`[0],`ModelEnd`[0]]. Thereby the indices refer to the values of the parameters `RowComp`, `ColumnComp`, `AngleComp`, `ScoreComp`, and `ModelComp`.

Example: The component model consists for three components. Two instances have been found on the image, where for one instance only two components (component 0 and component 2) could be found. Then the returned parameters could look like this:

<code>RowComp</code> = [100,200,300,150,250]	<code>ModelStart</code> = [0,3]
<code>ColumnComp</code> = [200,210,220,400,425]	<code>ModelEnd</code> = [2,4]
<code>AngleComp</code> = [0,0.1,-0.2,0.1,0.2]	<code>ModelComp</code> = [0,1,2,0,2]
<code>ScoreComp</code> = [1,1,1,1,1]	<code>Score</code> = [1,1]

From the right column it is visible, that in the left column:

- Values with index 0 to 2 correspond to the components 0 to 2 of instance 1.
- Values with index 3 to 4 correspond to the components 0 and 2 of instance 2.

Score: Score of the found instances of the component model.

`Score` contains the weighted mean of the component scores, the values in `ScoreComp`. The weighting is performed according to the number of model points within the respective component.

RowComp, ColumnComp, and AngleComp: The position (`RowComp`, `ColumnComp`) and rotation (`AngleComp`) of the model components of all found component model instances.

The coordinates `RowComp` and `ColumnComp` are the coordinates of the component origin (reference point) in the search image. The component origin depends on the model creation:

- with `create_trained_component_model` by training: The component origin is the center of gravity of the respective returned contour region in `ModelComponents` of the operator `train_model_components`.
- with `create_component_model` manually: The component origin is the center of gravity of the corresponding passed component region `ComponentRegions` of the operator `create_component_model`.

Since the relations between the components in `ComponentModelID` refer to this reference point, the origin of the components must not be modified by using `set_shape_model_origin`.

ScoreComp: Score of each found component instance.

The score is a number between 0 and 1, and is an approximate measure of how much of the component is visible in the image. If, for example, half of the component is occluded, the score cannot exceed 0.5.

ModelComp: Index of the found component.

The tuple contains the indices of the respective model components (see `create_component_model` and `train_model_components`, respectively). By this the values in `RowComp`, `ColumnComp`, `AngleComp`, and `ScoreComp` can be associated to the different model components. See also the example given for `ModelStart` and `ModelEnd`.

Information concerning the search

Internally, the shape-based matching is used for the component-based matching in order to search the individual components (see `find_shape_model`).

The domain of the `Image` determines the search space for the reference point, i.e., the allowed positions, of the root component.

Usually the component model is searched only within those points of the image domain in which the model fits completely into the image. This means that the components will not be found if they extend beyond the borders of the image, even if they would achieve a score greater than `MinScoreComp` (see above).

Note that, if for a certain pyramid level the component model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with `set_system('border_shape_models', 'true')`, which will cause components that extend beyond the image border to be found if they achieve a score greater than `MinScoreComp`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that this mode increases the runtime of the search.

Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on `NumMatches`. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for `NumMatches` set to 1 might be different from the match with the highest score returned when setting `NumMatches` to 0 or > 1 .

Recommendations

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise `NumMatches`, and then select the match with the highest score.

To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a subpixel extraction that applies a least-squares adjustment. If the subpixel extraction and/or the maximum object deformation is specified separately for each component, for each component in `ComponentModelID` exactly one value for the subpixel extraction must be passed in `SubPixelComp`. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain component no value for the maximum object deformation is passed, the component is searched without taking deformations into account. Further details can be found in the documentation of `find_shape_models`.

Parameters

- ▷ **Image** (input_object)(multichannel-)image $\leadsto$ object : byte / uint2
Input image in which the component model should be found.
- ▷ **ComponentModelID** (input_control) component_model $\leadsto$ handle
Handle of the component model.
- ▷ **RootComponent** (input_control) integer(-array) $\leadsto$ integer
Index of the root component.
Suggested values: `RootComponent` $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8}
- ▷ **AngleStartRoot** (input_control) angle.rad(-array) $\leadsto$ real
Smallest rotation of the root component
Default: -0.39
Suggested values: `AngleStartRoot` $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}

- ▷ **AngleExtentRoot** (input_control) angle.rad(-array) $\leadsto$ *real*
Extent of the rotation of the root component.
Default: 0.79
Suggested values: AngleExtentRoot $\in$ {6.28, 3.14, 1.57, 0.79, 0.39, 0.0}
Restriction: AngleExtentRoot ≥ 0
- ▷ **MinScore** (input_control) *real* $\leadsto$ *real*
Minimum score of the instances of the component model to be found.
Default: 0.5
Suggested values: MinScore $\in$ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: $0 \leq \text{MinScore} \ \&\& \ \text{MinScore} \leq 1$
- ▷ **NumMatches** (input_control) *integer* $\leadsto$ *integer*
Number of instances of the component model to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in$ {0, 1, 2, 3, 4, 5, 10, 20}
- ▷ **MaxOverlap** (input_control) *real* $\leadsto$ *real*
Maximum overlap of the instances of the component models to be found.
Default: 0.5
Suggested values: MaxOverlap $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: $0 \leq \text{MaxOverlap} \ \&\& \ \text{MaxOverlap} \leq 1$
- ▷ **IfRootNotFound** (input_control) *string* $\leadsto$ *string*
Behavior if the root component is missing.
Default: 'stop_search'
List of values: IfRootNotFound $\in$ {'stop_search', 'select_new_root'}
- ▷ **IfComponentNotFound** (input_control) *string* $\leadsto$ *string*
Behavior if a component is missing.
Default: 'prune_branch'
List of values: IfComponentNotFound $\in$ {'prune_branch', 'search_from_upper', 'search_from_best'}
- ▷ **PosePrediction** (input_control) *string* $\leadsto$ *string*
Pose prediction of components that are not found.
Default: 'none'
List of values: PosePrediction $\in$ {'none', 'from_neighbors', 'from_all'}
- ▷ **MinScoreComp** (input_control) *real*(-array) $\leadsto$ *real*
Minimum score of the instances of the components to be found.
Default: 0.5
Suggested values: MinScoreComp $\in$ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: $0 \leq \text{MinScoreComp} \ \&\& \ \text{MinScoreComp} \leq 1$
- ▷ **SubPixelComp** (input_control) *string*(-array) $\leadsto$ *string*
Subpixel accuracy of the component poses if not equal to 'none'.
Default: 'least_squares'
Suggested values: SubPixelComp $\in$ {'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3', 'max_deformation 4', 'max_deformation 5', 'max_deformation 6'}
- ▷ **NumLevelsComp** (input_control) *integer*(-array) $\leadsto$ *integer*
Number of pyramid levels for the components used in the matching (and lowest pyramid level to use if [|NumLevelsComp| = 2n](#)).
Default: 0
List of values: NumLevelsComp $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- ▷ **GreedinessComp** (input_control) real(-array) $\leadsto$ real
 “Greediness” of the search heuristic for the components (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: GreedinessComp $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: 0 $\leq$ GreedinessComp && GreedinessComp $\leq$ 1
- ▷ **ModelStart** (output_control) integer(-array) $\leadsto$ integer
 Start index of each found instance of the component model in the tuples describing the component matches.
- ▷ **ModelEnd** (output_control) integer(-array) $\leadsto$ integer
 End index of each found instance of the component model in the tuples describing the component matches.
- ▷ **Score** (output_control) real(-array) $\leadsto$ real
 Score of the found instances of the component model.
- ▷ **RowComp** (output_control) point.y(-array) $\leadsto$ real
 Row coordinate of the found component matches.
- ▷ **ColumnComp** (output_control) point.x(-array) $\leadsto$ real
 Column coordinate of the found component matches.
- ▷ **AngleComp** (output_control) angle.rad(-array) $\leadsto$ real
 Rotation angle of the found component matches.
- ▷ **ScoreComp** (output_control) real(-array) $\leadsto$ real
 Score of the found component matches.
- ▷ **ModelComp** (output_control) integer(-array) $\leadsto$ integer
 Index of the found components.

Result

If the parameter values are correct, the operator `find_component_model` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input image available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
gen_initial_components (
    ModelImage : InitialComponents : ContrastLow, ContrastHigh,
    MinSize, Mode, GenericName, GenericValue : )
```

Extract the initial components of a component model.

In general, there are two possibilities to use `gen_initial_components`. The first possibility should be chosen if the components of the component model are not known. Then `gen_initial_components`

automatically extracts the initial components of a component model from a model image. The second possibility can be chosen if the components of the component model are approximately known. Then `gen_initial_components` can be used to find suitable parameter values for the model feature extraction in `train_model_components` and `create_component_model`. Hence, the second possibility is comparable to the function of `inspect_shape_model` within the shape-based matching.

When using the first possibility, `gen_initial_components` extracts the initial components of a component model from a model image `ModelImage`. As already mentioned, this is especially useful if the components of the component model are not known. In this case, the resulting initial components can be used to automatically train the component model with `train_model_components`, which extracts the (final) model components and the relations between them. `gen_initial_components` returns the initial components in a region object tuple `InitialComponents` that contains a representation for each initial component in form of contour regions.

For the automatic determination of the initial components, the domain of the model image `ModelImage` must contain the entire compound object including all components. `Mode` specifies the method used for the automatic computation. Currently, only the mode `'connection'` is available. In this mode the automatic computation is performed in two steps: In the first step, features are extracted using the parameters `ContrastLow`, `ContrastHigh`, and `MinSize`. These three parameters define the contours of which the initial components should consist and should be chosen such that only the significant features of the model image are contained in the initial components. `ContrastLow` and `ContrastHigh` specify the gray value contrast of the points that should be contained in the initial components. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. The model image is segmented using a method similar to the hysteresis threshold method used in `edges_image`. Here, `ContrastLow` determines the lower threshold, while `ContrastHigh` determines the upper threshold. If the same value is passed for `ContrastLow` and `ContrastHigh` a simple thresholding operation is performed. For more information about the hysteresis threshold method, see `hysteresis_threshold`. `MinSize` can be used to select only significant features for the initial components based on the size of the connected contour regions, i.e., connected contour regions with fewer than `MinSize` points are suppressed.

The resulting connected contour regions are iteratively merged in the second step. For this, two contour regions are merged if the distance between both regions is smaller than a certain threshold (see below). Finally, the merged regions are returned in `InitialComponents` and can be used to train the component model by passing them to `train_model_components`.

To control the internal image processing, the parameters `GenericName` and `GenericValue` are used. This is done by passing the names of the control parameters to be changed in `GenericName` as a list of strings. In `GenericValue` the values are passed at the corresponding index positions.

Normally, none of the values needs to be changed. A change should only be applied in case of unsatisfying results of the automatic determination of the initial components. The two parameters that can be changed are `'merge_distance'` and `'merge_fraction'`; both are used during the iterative merging of contour regions (see above). First, the fraction of contour pixels of one contour region that at most have a distance of `'merge_distance'` from another contour region is computed. If this fraction exceeds the value that is passed in `'merge_fraction'` the two contour regions are merged. Consequently, the higher `'merge_distance'` and the lower `'merge_fraction'` is chosen the more contour regions are merged. The default value of `'merge_distance'` is 5 and the default value of `'merge_fraction'` is 0.5 (corresponds to 50 percent).

When using the second possibility, i.e., the components of the component model are approximately known, the training by using `train_model_components` can be performed without previously executing `gen_initial_components`. If this is desired, the initial components can be specified by the user and directly passed to `train_model_components`. Furthermore, if the components as well as the relative movements (relations) of the components are known, `gen_initial_components` as well as `train_model_components` need not be executed. In fact, by immediately passing the components as well as the relations to `create_component_model`, the component model can be created without any training. In both cases, however, `gen_initial_components` can be used to evaluate the effect of the feature extraction parameters `ContrastLow`, `ContrastHigh`, and `MinSize` of `train_model_components` and `create_component_model`, and hence to find suitable parameter values for a certain application.

For this, the image regions for the (initial) components must be explicitly given, i.e., for each (initial) component a separate image from which the (initial) component should be created is passed. In this case, `ModelImage` contains multiple image objects. The domain of each image object is used as the region of interest for calculating the corresponding (initial) component. The image matrix of all image objects in the tuple must be identical, i.e., `ModelImage` cannot be constructed in an arbitrary manner using `concat_obj`, but must be created from the same image using `add_channels` or equivalent calls. If this is not the case, an error message is returned. If

the parameters `ContrastLow`, `ContrastHigh`, or `MinSize` only contain one element, this value is applied to the creation of all (initial) components. In contrast, if different values for different (initial) components should be used, tuples of values can be passed for these three parameters. In this case, the tuples must have a length that corresponds to the number of (initial) components, i.e., the number of image objects in `ModelImage`. The contour regions of the (initial) components are returned in `InitialComponents`.

Thus, the second possibility is equivalent to the function of `inspect_shape_model` within the shape-based matching. However, in contrast to `inspect_shape_model`, `gen_initial_components` does not return the contour regions on multiple image pyramid levels. Therefore, if the number of pyramid levels to be used should be chosen manually, preferably `inspect_shape_model` should be called individually for each (initial) component.

For both described possibilities the parameters `ContrastLow`, `ContrastHigh`, and `MinSize` can be automatically determined. If both hysteresis threshold should be automatically determined, both `ContrastLow` and `ContrastHigh` must be set to `'auto'`. In contrast, if only one threshold value should be determined, `ContrastLow` must be set to `'auto'` while `ContrastHigh` must be set to an arbitrary value different from `'auto'`.

If the input image `ModelImage` has one channel the representation of the model is created with the method that is used in `create_component_model` or `create_trained_component_model` for the metrics `'use_polarity'`, `'ignore_global_polarity'`, and `'ignore_local_polarity'`. If the input image has more than one channel the representation is created with the method that is used for the metric `'ignore_color_polarity'`.

Parameters

- ▷ **ModelImage** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / uint2
Input image from which the initial components should be extracted.
- ▷ **InitialComponents** (output_object) region-array $\leadsto$ *object*
Contour regions of initial components.
- ▷ **ContrastLow** (input_control) integer(-array) $\leadsto$ *integer* / *string*
Lower hysteresis threshold for the contrast of the initial components in the image.
Default: `'auto'`
Suggested values: `ContrastLow` $\in$ `{'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}`
Restriction: `ContrastLow` > 0
- ▷ **ContrastHigh** (input_control) integer(-array) $\leadsto$ *integer* / *string*
Upper hysteresis threshold for the contrast of the initial components in the image.
Default: `'auto'`
Suggested values: `ContrastHigh` $\in$ `{'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}`
Restriction: `ContrastHigh` > 0 && `ContrastHigh` $\geq$ `ContrastLow`
- ▷ **MinSize** (input_control) integer(-array) $\leadsto$ *integer* / *string*
Minimum size of the initial components.
Default: `'auto'`
Suggested values: `MinSize` $\in$ `{'auto', 0, 5, 10, 20, 30, 40}`
Restriction: `MinSize` ≥ 0
- ▷ **Mode** (input_control) string $\leadsto$ *string*
Type of automatic segmentation.
Default: `'connection'`
List of values: `Mode` $\in$ `{'connection'}`
- ▷ **GenericName** (input_control) string(-array) $\leadsto$ *string*
Names of optional control parameters.
Default: `[]`
List of values: `GenericName` $\in$ `{'merge_distance', 'merge_fraction'}`
- ▷ **GenericValue** (input_control) number(-array) $\leadsto$ *real* / *integer*
Values of optional control parameters.
Default: `[]`

Example

- * First example that shows the use of `gen_initial_components` to automatically
- * extract the initial components from a model image.
- * Get the model image.

```

read_image (Image, 'model_image.tif')
* Define the entire model region.
gen_rectangle1 (ModelRegion, 119, 106, 330, 537)
reduce_domain (Image, ModelRegion, ModelImage)
* Automatically generate the initial components.
gen_initial_components (ModelImage, InitialComponents, 40, 40, 20, \
                        'connection', [], [])
* Extract the model components and train the relations.
train_model_components (ModelImage, InitialComponents, TrainingImages, \
                        ModelComponents, 40, 40, 20, 0.85, 0, 0, rad(15), \
                        'speed', 'rigidity', 0.2, 0.5, ComponentTrainingID)
* Create the component model based on the training result.
create_trained_component_model (ComponentTrainingID, -rad(30), rad(60), 10, \
                                0.8, 'auto', 'auto', 'none', \
                                'use_polarity', 'false', ComponentModelID, \
                                RootRanking)

* Second example that shows the use of gen_initial_components to evaluate
* the effect of the feature extraction parameters.

* Get the model image.
read_image (ModelImage, 'model_image.tif')
* Define the regions for the components.
gen_rectangle2 (ComponentRegions, 318, 109, -1.62, 34, 19)
gen_rectangle2 (Rectangle2, 342, 238, -1.63, 32, 17)
gen_rectangle2 (Rectangle3, 355, 505, 1.41, 25, 17)
concat_obj (ComponentRegions, Rectangle2, ComponentRegions)
concat_obj (ComponentRegions, Rectangle3, ComponentRegions)
add_channels (ComponentRegions, ModelImage, ModelImageReduced)
gen_initial_components (ModelImageReduced, InitialComponents, 15, 40, 15, \
                        'connection', [], [])
* Create the component model by explicitly specifying the relations.
create_component_model (ModelImage, ComponentRegions, 20, 20, rad(25), 0, \
                        rad(360), 15, 40, 15, 10, 0.8, 'auto', 'auto', \
                        'none', 'use_polarity', 'false', ComponentModelID, \
                        RootRanking)

```

Result

If the parameter values are correct, the operator `gen_initial_components` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`draw_region`, `add_channels`, `reduce_domain`

Possible Successors

`train_model_components`

Alternatives

`inspect_shape_model`

Module

Matching

```
get_component_model_params ( : : ComponentModelID : MinScoreComp,
                             RootRanking, ShapeModelIDs )
```

Return the parameters of a component model.

The operator `get_component_model_params` returns the parameters of the component model `ComponentModelID`. In particular, this output can be used to check the parameters `RootRanking` and `MinScoreComp` after reading the component model with `read_component_model`. Additionally, the operator returns the shape model IDs `ShapeModelIDs` of the model components. The order of the returned shape model IDs corresponds to the indices of the components within the component model `ComponentModelID`. The IDs can be used to query their shape model parameters with `get_shape_model_params`.

Parameters

- ▷ **ComponentModelID** (input_control) component_model $\leadsto$ *handle*
Handle of the component model.
- ▷ **MinScoreComp** (output_control) real(-array) $\leadsto$ *real*
Minimum score of the instances of the components to be found.
- ▷ **RootRanking** (output_control) integer(-array) $\leadsto$ *integer*
Ranking of the model components expressing their suitability to act as root component.
- ▷ **ShapeModelIDs** (output_control) shape_model(-array) $\leadsto$ *handle*
Handles of the shape models of the individual model components.

Example

```
read_component_model ('pliers.cbm', ComponentModelID)
get_component_model_params (ComponentModelID, MinScoreComp, RootRanking, \
                           ShapeModelIDs)
for i := 0 to |ShapeModelIDs|-1 by 1
    get_generic_shape_model_param (ShapeModelIDs[i], 'min_score', \
    GenParamValue)
endfor
```

Result

If the handle of the component model is valid, the operator `get_component_model_params` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

`get_generic_shape_model_param`

Module

Matching

```
get_component_model_tree ( : Tree, Relations : ComponentModelID,
                             RootComponent, Image : StartNode, EndNode, Row, Column, Phi,
                             Length1, Length2, AngleStart, AngleExtent )
```

Return the search tree of a component model.

`get_component_model_tree` returns the search tree `Tree` and the associated relations `Relations` of the component model that is passed in `ComponentModelID` in form of regions as well as in numerical form. `get_component_model_tree` is particularly useful in order to visualize the search order of the components, which was automatically computed in `create_trained_component_model` or `create_component_model`.

Because the search tree depends on the selected root component, the root component must be passed in `RootComponent`. The nodes in the tree `Tree` represent the model components, the connecting lines between the nodes indicate which components are searched relative to each other. The position of the nodes corresponds to the position of the components in the model image (if `Image = 'model_image'` or `Image = 0`) or in a training image (if `Image ≥ 1`). In the latter case, the component model must have been created based on a component training result with `create_trained_component_model`.

Let n be the number of components in `ComponentModelID`. The region object tuple `Relations` of length n is designed as follows: For each component a separate region is returned. The positions of all components in the image are represented by circles with a radius of 3 pixels. For each component other than the root component `RootComponent`, additionally the position relation and the orientation relation relative to the predecessor component in the search tree are represented. The position relation is represented by a rectangle, the orientation relation is represented by a circle sector with a radius of 30 pixels. The center of the circle is placed at the mean relative position of the component. The rectangle describes the movement of the reference point of the respective component relative to the pose of its predecessor component, the circle sector describes the variation of the relative orientation. A relative orientation of 0 corresponds to the relative orientation of both components in the model image.

In addition to the regions, the search tree as well as the associated relations are also returned in numerical form. The search tree is described by the two tuples `StartNode` and `EndNode`, both of length n , which contain the start and the end node of all arcs in the tree. The nodes contain the indices of the components. This means that during the search the component that is described by the end node is searched relative to the pose of the component that is described by the start node (predecessor component). Since the root component is not searched relative to any other component, and hence does not have a predecessor component, the associated start node is set to -1 . The relations are returned in `Row`, `Column`, `Phi`, `Length1`, `Length2`, `AngleStart`, and `AngleExtent`. These parameters are tuples of length n , and contain the relations of all components relative to their associated predecessor component, where the order of the values within the tuples is determined by the index of the corresponding component. The position relation is described by the parameters of the corresponding rectangle `Row`, `Column`, `Phi`, `Length1`, and `Length2` (see `gen_rectangle2`). The orientation relation is described by the starting angle `AngleStart` and the angle extent `AngleExtent`.

For the root component as well as for components that do not have a predecessor in the current image or that have not been found in the current image, an empty region is returned and the corresponding values of the seven parameters are set to 0.

Parameters

- ▷ **Tree** (output_object) region $\leadsto$ object
Search tree.
- ▷ **Relations** (output_object) region-array $\leadsto$ object
Relations of components that are connected in the search tree.
- ▷ **ComponentModelID** (input_control) component_model $\leadsto$ handle
Handle of the component model.
- ▷ **RootComponent** (input_control) integer(-array) $\leadsto$ integer
Index of the root component.
Suggested values: `RootComponent` $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8}
- ▷ **Image** (input_control) string $\leadsto$ string / integer
Image for which the tree is to be returned.
Default: `'model_image'`
Suggested values: `Image` $\in$ {'model_image', 0, 1, 2, 3, 4, 5, 6, 7, 8}
- ▷ **StartNode** (output_control) integer(-array) $\leadsto$ integer
Component index of the start node of an arc in the search tree.
- ▷ **EndNode** (output_control) integer(-array) $\leadsto$ integer
Component index of the end node of an arc in the search tree.
- ▷ **Row** (output_control) rectangle2.center.y(-array) $\leadsto$ real
Row coordinate of the center of the rectangle representing the relation.

- ▷ **Column** (output_control) rectangle2.center.x(-array) $\leadsto$ *real*
Column index of the center of the rectangle representing the relation.
- ▷ **Phi** (output_control) rectangle2.angle.rad(-array) $\leadsto$ *real*
Orientation of the rectangle representing the relation (radians).
Assertion: - $\pi / 2 < \text{Phi} \ \&\& \ \text{Phi} \leq \pi / 2$
- ▷ **Length1** (output_control) rectangle2.hwidth(-array) $\leadsto$ *real*
First radius (half length) of the rectangle representing the relation.
Assertion: Length1 $\geq$ 0.0
- ▷ **Length2** (output_control) rectangle2.hheight(-array) $\leadsto$ *real*
Second radius (half width) of the rectangle representing the relation.
Assertion: Length2 $\geq$ 0.0 && Length2 $\leq$ Length1
- ▷ **AngleStart** (output_control) angle.rad(-array) $\leadsto$ *real*
Smallest relative orientation angle.
- ▷ **AngleExtent** (output_control) angle.rad(-array) $\leadsto$ *real*
Extent of the relative orientation angle.

Example

```
* Read the model image.
read_image (ModelImage, 'model_image.tif')
* Describe the model components.
gen_rectangle2 (ComponentRegions, 318, 109, -1.62, 34, 19)
gen_rectangle2 (Rectangle2, 342, 238, -1.63, 32, 17)
gen_rectangle2 (Rectangle3, 355, 505, 1.41, 25, 17)
concat_obj (ComponentRegions, Rectangle2, ComponentRegions)
concat_obj (ComponentRegions, Rectangle3, ComponentRegions)
* Create the component model.
create_component_model (ModelImage, ComponentRegions, 20, 20, rad(25), 0, \
    rad(360), 15, 40, 15, 10, 0.8, 0, 0, 'none', \
    'use_polarity', 'true', ComponentModelID, \
    RootRanking)
* Get the component model tree.
get_component_model_tree (Tree, Relations, ComponentModelID, RootRanking, \
    'model_image', StartNode, EndNode, Row, Column, \
    Phi, Length1, Length2, AngleStart, AngleExtent)

dev_set_colored (12)
dev_display (ModelImage)
dev_display (Tree)
dev_display (Relations)
```

Result

If the parameters are valid, the operator `get_component_model_tree` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
get_component_relations ( : Relations : ComponentTrainingID,
                          ReferenceComponent, Image : Row, Column, Phi, Length1, Length2,
                          AngleStart, AngleExtent )
```

Return the relations between the model components that are contained in a training result.

`get_component_relations` returns the relations between model components after training them with `train_model_components`. With the parameter `ReferenceComponent`, you can select a reference component. `get_component_relations` then returns the relations between the reference component and all other components in the model image (if `Image = 'model_image'` or `Image = 0`) or in a training image (if `Image ≥ 1`). In order to obtain the relations in the i th training image, `Image` must be set to i . The result of the training returned by `train_model_components` must be passed in `ComponentTrainingID`. `ReferenceComponent` describes the index of the reference component and must be within the range of 0 and $n-1$, if n is the number of model components (see `train_model_components`).

The relations are returned in form of regions in `Relations` as well as in form of numerical values in `Row`, `Column`, `Phi`, `Length1`, `Length2`, `AngleStart`, and `AngleExtent`.

The region object tuple `Relations` is designed as follows. For each component a separate region is returned. Consequently, `Relations` contains n regions, where the order of the regions within the tuple is determined by the index of the corresponding components. The positions of all components in the image are represented by circles with a radius of 3 pixels. For each component other than the reference component `ReferenceComponent`, additionally the position relation and the orientation relation relative to the reference component are represented. The position relation is represented by a rectangle and the orientation relation is represented by a circle sector with a radius of 30 pixels. The center of the circle is placed at the mean relative position of the component. The rectangle describes the movement of the reference point of the respective component relative to the pose of the reference component, while the circle sector describes the variation of the relative orientation (see `train_model_components`). A relative orientation of 0 corresponds to the relative orientation of both components in the model image. If both components appear in the same relative orientation in all images, the circle sector consequently degenerates to a straight line.

In addition to the region object tuple `Relations`, the relations are also returned in form of numerical values in `Row`, `Column`, `Phi`, `Length1`, `Length2`, `AngleStart`, and `AngleExtent`. These parameters are tuples of length n and contain the relations of all components relative to the reference component, where the order of the values within the tuples is determined by the index of the corresponding component. The position relation is described by the parameters of the corresponding rectangle `Row`, `Column`, `Phi`, `Length1`, and `Length2` (see `gen_rectangle2`). The orientation relation is described by the starting angle `AngleStart` and the angle extent `AngleExtent`. For the reference component only the position within the image is returned in `Row` and `Column`. All other values are set to 0.

If the reference component has not been found in the current image, an array of empty regions is returned and the corresponding parameter values are set to 0.

The operator `get_component_relations` is particularly useful in order to visualize the result of the training that was performed with `train_model_components`. With this, it is possible to evaluate the variations that are contained in the training images. Sometimes it might be reasonable to restart the training with `train_model_components` while using a different set of training images.

Parameters

- ▷ **Relations** (output_object) region(-array) $\leadsto$ object
Region representation of the relations.
- ▷ **ComponentTrainingID** (input_control) component_training $\leadsto$ handle
Handle of the training result.
- ▷ **ReferenceComponent** (input_control) integer $\leadsto$ integer
Index of reference component.
Restriction: `ReferenceComponent ≥ 0`
- ▷ **Image** (input_control) string $\leadsto$ string / integer
Image for which the component relations are to be returned.
Default: 'model_image'
Suggested values: `Image ∈ {'model_image', 0, 1, 2, 3, 4, 5, 6, 7, 8}`
- ▷ **Row** (output_control) rectangle2.center.y(-array) $\leadsto$ real
Row coordinate of the center of the rectangle representing the relation.

- ▷ **Column** (output_control) rectangle2.center.x(-array) $\leadsto$ *real*
Column index of the center of the rectangle representing the relation.
- ▷ **Phi** (output_control) rectangle2.angle.rad(-array) $\leadsto$ *real*
Orientation of the rectangle representing the relation (radians).
Assertion: $-\pi/2 < \text{Phi} \ \&\& \ \text{Phi} \leq \pi/2$
- ▷ **Length1** (output_control) rectangle2.hwidth(-array) $\leadsto$ *real*
First radius (half length) of the rectangle representing the relation.
Assertion: $\text{Length1} \geq 0.0$
- ▷ **Length2** (output_control) rectangle2.hheight(-array) $\leadsto$ *real*
Second radius (half width) of the rectangle representing the relation.
Assertion: $\text{Length2} \geq 0.0 \ \&\& \ \text{Length2} \leq \text{Length1}$
- ▷ **AngleStart** (output_control) angle.rad(-array) $\leadsto$ *real*
Smallest relative orientation angle.
- ▷ **AngleExtent** (output_control) angle.rad(-array) $\leadsto$ *real*
Extent of the relative orientation angles.

Result

If the handle of the training result is valid, the operator `get_component_relations` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
get_found_component_model ( : FoundComponents : ComponentModelID,
    ModelStart, ModelEnd, RowComp, ColumnComp, AngleComp, ScoreComp,
    ModelComp, ModelMatch, MarkOrientation : RowCompInst,
    ColumnCompInst, AngleCompInst, ScoreCompInst )
```

Return the components of a found instance of a component model.

`get_found_component_model` returns the components of a found instance of the component model [ComponentModelID](#) in form of contour regions in [FoundComponents](#) as well as in numerical form.

The operator `get_found_component_model` is particularly useful in order to visualize the matches that have been obtained by [find_component_model](#).

The pose of the returned components corresponds to their pose in the search image as returned by [find_component_model](#). Hence, the parameters [ModelStart](#), [ModelEnd](#), [RowComp](#), [ColumnComp](#), [AngleComp](#), [ScoreComp](#), and [ModelComp](#) must be passed to `get_found_component_model` as they have been returned by [find_component_model](#). In [ModelMatch](#) the index of the found instance of the component model must be passed. Consequently, [ModelMatch](#) must lie within the range between 0 and $m-1$, where m is the number of elements in [ModelStart](#) and [ModelEnd](#), and hence corresponds to the number of found model instances. For example, if the best match should be returned, [ModelMatch](#) should be set to 0.

When dealing with rotationally symmetric components, one may wish to mark the current orientation of the found component. This can be achieved by setting [MarkOrientation](#) to `'true'`. In this case, the contour region of each component is complemented by an arrow at its reference point that points in the reference direction.

The reference direction of a component is based on the orientation of the component in the model image (see [train_model_components](#) or [create_component_model](#)) and is represented by an arrow that starts at the reference point and points to the right in the horizontal direction.

For convenience, the pose parameters as well as the score of each component of the found model instance are additionally returned in numerical form in [RowCompInst](#), [ColumnCompInst](#), [AngleCompInst](#), and [ScoreCompInst](#). The four tuples are always of length n , where n is the number of components in the component model [ComponentModelID](#). If a component could not be found during the search, an empty region is passed in the corresponding element of [FoundComponents](#) and the value of the corresponding element in [RowCompInst](#), [ColumnCompInst](#), [AngleCompInst](#), and [ScoreCompInst](#) is set to 0.

Parameters

- ▷ **FoundComponents** (output_object)region-array $\leadsto$ object
Found components of the selected component model instance.
- ▷ **ComponentModelID** (input_control) component_model $\leadsto$ handle
Handle of the component model.
- ▷ **ModelStart** (input_control)integer(-array) $\leadsto$ integer
Start index of each found instance of the component model in the tuples describing the component matches.
- ▷ **ModelEnd** (input_control)integer(-array) $\leadsto$ integer
End index of each found instance of the component model to the tuples describing the component matches.
- ▷ **RowComp** (input_control)point.y(-array) $\leadsto$ real
Row coordinate of the found component matches.
- ▷ **ColumnComp** (input_control)point.x(-array) $\leadsto$ real
Column coordinate of the found component matches.
- ▷ **AngleComp** (input_control) angle.rad(-array) $\leadsto$ real
Rotation angle of the found component matches.
- ▷ **ScoreComp** (input_control) real(-array) $\leadsto$ real
Score of the found component matches.
- ▷ **ModelComp** (input_control) integer(-array) $\leadsto$ integer
Index of the found components.
- ▷ **ModelMatch** (input_control)integer $\leadsto$ integer
Index of the found instance of the component model to be returned.
- ▷ **MarkOrientation** (input_control) string $\leadsto$ string
Mark the orientation of the components.
Default: 'false'
List of values: MarkOrientation $\in$ {'true', 'false'}
- ▷ **RowCompInst** (output_control) point.y(-array) $\leadsto$ real
Row coordinate of all components of the selected model instance.
- ▷ **ColumnCompInst** (output_control) point.x(-array) $\leadsto$ real
Column coordinate of all components of the selected model instance.
- ▷ **AngleCompInst** (output_control) angle.rad(-array) $\leadsto$ real
Rotation angle of all components of the selected model instance.
- ▷ **ScoreCompInst** (output_control) real(-array) $\leadsto$ real
Score of all components of the selected model instance.

Example

```
* Read a component model from file.
read_component_model ('pliers.cpm', ComponentModelID)
* Find the component model in a run-time image.
read_image (SearchImage, 'search_image.tif')
find_component_model (SearchImage, ComponentModelID, RootRanking, 0, \
    rad(360), 0.5, 0, 0.5, 'stop_search', \
    'prune_branch', 'none', 0.8, 'least_squares', 0, \
    0.8, ModelStart, ModelEnd, Score, RowComp, \
    ColumnComp, AngleComp, ScoreComp, ModelComp)
* Visualize the found instances.
for i := 0 to |ModelStart|-1 by 1
```

```

get_found_component_model (FoundComponents, ComponentModelID, \
                          ModelStart, ModelEnd, RowComp, ColumnComp, \
                          AngleComp, ScoreComp, ModelComp, i, 'false', \
                          RowCompInst, ColumnCompInst, AngleCompInst, \
                          ScoreCompInst)

dev_display (FoundComponents)
endfor

```

Result

If the parameters are valid, the operator `get_found_component_model` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

[train_model_components](#), [create_component_model](#)

Module

Matching

<pre> get_training_components (: TrainingComponents : ComponentTrainingID, Components, Image, MarkOrientation : Row, Column, Angle, Score) </pre>
--

Return the initial or model components in a certain image.

`get_training_components` returns all initial components (if `Components` = `'initial_components'`) or all model components (if `Components` = `'model_components'`) in `TrainingComponents` in form of contour regions as well as in numerical form. Alternatively, by directly passing the index of an initial component, all found poses of that initial component (i.e., the poses before solving the ambiguities in `train_model_components`) are returned.

The pose of the returned components corresponds to their pose in the model image (if `Image` = `'model_image'` or `Image` = 0) or in a training image (if `Image` ≥ 1). In order to obtain the components in the pose at which they were found in the *i*th training image, `Image` must be set to *i*. Furthermore, when dealing with rotationally symmetric components, one may wish to mark the current orientation of the found component. This can be achieved by setting `MarkOrientation` to `'true'`. In this case, the contour region of each component is complemented by an arrow at its reference point pointing in the reference direction. The reference direction of a component is based on the orientation of the component in the model image and is represented by an arrow that starts at the reference point and points to the right in the horizontal direction.

In addition to the contour regions, the pose and the score of all found components is returned in `Row`, `Column`, `Angle`, and `Score` (see [find_shape_model](#)). If `Components` was set to `'initial_components'` or `'model_components'`, the tuples `TrainingComponents`, `Row`, `Column`, `Angle`, and `Score` always contain the same number of elements as initial components or model components contained in `ComponentTrainingID`, respectively. If one component was not found in the image, an empty region is returned in the corresponding element of `TrainingComponents` and the elements of the four output control parameters are set to the value 0. In contrast, if the index of an initial component is passed in `Components`, these tuples contain as many elements as matches of the corresponding initial component were found in the image.

The operator `get_training_components` is particularly useful in order to visualize the result of the training `ComponentTrainingID`, which was performed with `train_model_components`. With this, it is possible to evaluate the suitability of the training images or to inspect the influence of the parameters of `train_model_components`. Sometimes it might be reasonable to restart the training with `train_model_components` using a different set of training images or after adjusting the parameters.

Parameters

- ▷ **TrainingComponents** (output_object)region(-array) $\leadsto$ *object*
Contour regions of the initial components or of the model components.
- ▷ **ComponentTrainingID** (input_control)component_training $\leadsto$ *handle*
Handle of the training result.
- ▷ **Components** (input_control)string $\leadsto$ *string / integer*
Type of returned components or index of an initial component.
Default: 'model_components'
Suggested values: Components $\in$ {'model_components', 'initial_components', 0, 1, 2, 3, 4, 5}
- ▷ **Image** (input_control)string $\leadsto$ *string / integer*
Image for which the components are to be returned.
Default: 'model_image'
Suggested values: Image $\in$ {'model_image', 0, 1, 2, 3, 4, 5, 6, 7, 8}
- ▷ **MarkOrientation** (input_control)string $\leadsto$ *string*
Mark the orientation of the components.
Default: 'false'
List of values: MarkOrientation $\in$ {'true', 'false'}
- ▷ **Row** (output_control)point.y(-array) $\leadsto$ *real*
Row coordinate of the found instances of all initial components or model components.
- ▷ **Column** (output_control)point.x(-array) $\leadsto$ *real*
Column coordinate of the found instances of all initial components or model components.
- ▷ **Angle** (output_control)angle.rad(-array) $\leadsto$ *real*
Rotation angle of the found instances of all components.
- ▷ **Score** (output_control)real(-array) $\leadsto$ *real*
Score of the found instances of all components.

Example

```

* Get the model image.
read_image (ModelImage, 'model_image.tif')
* Define the regions for the initial components.
gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
* Get the training images.
gen_empty_obj (TrainingImages)
for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-'+i+'.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
endfor
* Extract the model components and train the relations.
train_model_components (ModelImage, InitialComponentRegions, \
    TrainingImages, ModelComponents, 22, 60, 30, 0.6, \
    0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.4, \
    ComponentTrainingID)
* Visualize the result of the training.
count_obj (InitialComponentRegions, NumInitComp)
count_obj (TrainingImages, NumTrainings)
for i := 1 to NumTrainings by 1
    select_obj (TrainingImages, TrainingImage, i)
    for j := 0 to NumInitComp-1 by 1
        * Visualize the ambiguous poses of each initial component.
        get_training_components (TrainingComponents, ComponentTrainingID, \
            j, i, 'false', Row, Column, Angle, Score)
    
```

```

endfor
* Visualize the final poses of the initial components.
get_training_components (TrainingComponents, ComponentTrainingID, \
                        'initial_components', i, 'false', \
                        Row, Column, Angle, Score)
* Visualize the final poses of the model components.
get_training_components (TrainingComponents, ComponentTrainingID, \
                        'model_components', i, 'false', \
                        Row, Column, Angle, Score)
endifor

```

Result

If the handle of the training result is valid, the operator `get_training_components` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`train_model_components`

Possible Successors

`train_model_components`

See also

`cluster_model_components`

Module

Matching

```

inspect_clustered_components (
    : ModelComponents : ComponentTrainingID, AmbiguityCriterion,
    : MaxContourOverlap, ClusterThreshold : )

```

Inspect the rigid model components obtained from the training.

`inspect_clustered_components` creates a representation of the rigid model components based on the training result `ComponentTrainingID` in form of contour regions. The resulting rigid model components are computed depending on the criterion that is used to solve the ambiguities `AmbiguityCriterion`, the maximum allowable contour overlap `MaxContourOverlap`, and the cluster threshold `ClusterThreshold` (see `train_model_components`). The cluster threshold, for example, influences the merging of the initial components. The greater the threshold is chosen, the fewer initial components are merged. The determined rigid model components are returned in `ModelComponents`.

Hence, after the components have been trained once by using `train_model_components`, `inspect_clustered_components` can be used to estimate the effect of different values for the parameters `AmbiguityCriterion`, `MaxContourOverlap`, and `ClusterThreshold` without performing the complete training procedure several times. Once the desired parameter values have been found, they can be efficiently adopted into the training result by using `cluster_model_components`.

Parameters

- ▷ **ModelComponents** (output_object) region(-array) $\leadsto$ *object*
Contour regions of rigid model components.
- ▷ **ComponentTrainingID** (input_control) component_training $\leadsto$ *handle*
Handle of the training result.
- ▷ **AmbiguityCriterion** (input_control) string $\leadsto$ *string*
Criterion for solving the ambiguities.
Default: 'rigidity'
List of values: `AmbiguityCriterion` $\in$ {'distance', 'orientation', 'distance_orientation', 'rigidity'}

- ▷ **MaxContourOverlap** (input_control) real $\leadsto$ real
Maximum contour overlap of the found initial components.
Default: 0.2
Suggested values: MaxContourOverlap $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: 0 <= MaxContourOverlap && MaxContourOverlap <= 1
- ▷ **ClusterThreshold** (input_control) real $\leadsto$ real
Threshold for clustering the initial components.
Default: 0.5
Suggested values: ClusterThreshold $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: 0 <= ClusterThreshold && ClusterThreshold <= 1

Example

```
* Get the model image.
read_image (ModelImage, 'model_image.tif')
* Define the regions for the initial components.
gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)

```
modify_component_relations ( : : ComponentTrainingID,
    ReferenceComponent, ToleranceComponent, PositionTolerance,
    AngleTolerance : )
```

Modify the relations within a training result.

`modify_component_relations` modifies the relations between the model components within the component training result `ComponentTrainingID`. The selection of the relation(s) that should be changed is performed by setting `ReferenceComponent` and `ToleranceComponent`, respectively. This means that the relative movement of component `ToleranceComponent` with respect to the component `ReferenceComponent` is modified.

The size of the change is specified as follows: By specifying a position tolerance `PositionTolerance`, the semi-axes of the rectangle that describes the reference point's movement (see `train_model_components`) are enlarged by `PositionTolerance` pixels. Accordingly, by specifying an orientation tolerance `AngleTolerance`, the angle range that describes the variation of the relative orientation (see `train_model_components`) is enlarged by `AngleTolerance` to both sides. Consequently, negative tolerance values lead to a decreased size of the relations. The operator `modify_component_relations` is particularly useful when the training images that were used during the training do not cover the entire spectrum of the relative movements.

In order to select the relations that should be modified, values for `ReferenceComponent` and `ToleranceComponent` can be passed in one of the following ways: For each of both parameters either one value, several values, or the string `'all'` can be passed. The following table summarizes the different possibilities by giving the affected relations for different combinations of parameter values. Here, four model components are assumed (0, 1, 2, and 3). If, for example, `ReferenceComponent` is set to 0 and `ToleranceComponent` is set to 1, then the relation (0,1), which corresponds to the relative movement of component 1 with respect to component 0, will be modified.

ReferenceComponent	ToleranceComponent	Affected Relation(s)
'all'	'all'	(0,1) (0,2) (0,3) (1,0) (1,2) (1,3) (2,0) (2,1) (2,3) (3,0) (3,1) (3,2)
'all'	[1,2]	(0,1) (0,2) (1,2) (2,1) (3,1) (3,2)
[0,1]	'all'	(0,1) (0,2) (0,3) (1,0) (1,2) (1,3)
0	1	(0,1)
0	[1,2]	(0,1) (0,2)
[0,1]	2	(0,2) (1,2)
[0,1,2]	[1,2,3]	(0,1) (1,2) (2,3)

The number of tolerance values passed in `PositionTolerance` and `AngleTolerance` must be either 1 or be equal to the number of affected relations. In the former case all affected relations are modified by the same value, whereas in the latter case each relation can be modified individually by passing different values within a tuple.

Parameters

- ▷ **ComponentTrainingID** (input_control) component_training $\leadsto$ *handle*
Handle of the training result.
- ▷ **ReferenceComponent** (input_control) string(-array) $\leadsto$ *string* / integer
Model component(s) relative to which the movement(s) should be modified.
Default: 'all'
Suggested values: ReferenceComponent $\in$ {'all', 0, 1, 2, 3, 4, 5, 6}
- ▷ **ToleranceComponent** (input_control) string(-array) $\leadsto$ *string* / integer
Model component(s) of which the relative movement(s) should be modified.
Default: 'all'
Suggested values: ToleranceComponent $\in$ {'all', 0, 1, 2, 3, 4, 5, 6}
- ▷ **PositionTolerance** (input_control) real(-array) $\leadsto$ *real*
Change of the position relation in pixels.
Suggested values: PositionTolerance $\in$ {1.0, 2.0, 3.0, 4.0, 5.0, 10.0, 20.0, 30.0}
- ▷ **AngleTolerance** (input_control) angle.rad(-array) $\leadsto$ *real*
Change of the orientation relation in radians.
Suggested values: AngleTolerance $\in$ {0.017, 0.035, 0.052, 0.070, 0.087, 0.175, 0.349}

Result

If the handle of the training result is valid, the operator `modify_component_relations` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ComponentTrainingID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

read_component_model (: : FileName : ComponentModelID)

Read a component model from a file.

The operator `read_component_model` reads a component model, which has been written with `write_component_model`, from the file `FileName` and returns it in `ComponentModelID`. The default HALCON file extension for the component model is 'cbm'.

	Parameters
▷ FileName (input_control)filename.read $\leadsto$ string	
File name.	
File extension: .cbm	
▷ ComponentModelID (output_control)component_model $\leadsto$ handle	
Handle of the component model.	

	Result
If the file name is valid, the operator <code>read_component_model</code> returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.	

	Execution Information
• Multithreading type: reentrant (runs in parallel with non-exclusive operators).	
• Multithreading scope: global (may be called from any thread).	
• Processed without parallelization.	

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

read_training_components (: : FileName : ComponentTrainingID)
--

Read a component training result from a file.

The operator `read_training_components` reads a component training result, which has been written with `write_training_components`, from the file `FileName` and returns it in `ComponentTrainingID`. The default HALCON file extension for the component training result is 'ct'.

Parameters

- ▷ **FileName** (input_control)filename.read ~> *string*
File name.
File extension: .ct
- ▷ **ComponentTrainingID** (output_control)component_training ~> *handle*
Handle of the training result.

Result

If the file name is valid, the operator `read_training_components` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

```
serialize_component_model (  
    : : ComponentModelID : SerializedItemHandle )
```

Serialize a component model.

`serialize_component_model` serializes the data of a component model (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The same data that is written in a file by [write_component_model](#) is converted to a serialized item. The component model is defined by the handle [ComponentModelID](#). The serialized component model is returned by the handle [SerializedItemHandle](#) and can be deserialized by [deserialize_component_model](#).

Parameters

- ▷ **ComponentModelID** (input_control)component_model ~> *handle*
Handle of the component model.
- ▷ **SerializedItemHandle** (output_control)serialized_item ~> *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_component_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Train components and relations for the component-based matching.

`train_model_components` extracts the final (rigid) model components and trains their mutual relations, i.e., their relative movements, on the basis of the initial components by considering several training images. The result of the training is returned in the handle `ComponentTrainingID`. The training result can be subsequently used to create the actual component model using `create_trained_component_model`.

`train_model_components` should be used in cases where the relations of the components are not known and should be trained automatically. In contrast, if the relations are known no training needs to be performed with `train_model_components`. Instead, the component model can be directly created with `create_component_model`.

If the initial components have been automatically created by using `gen_initial_components`, `InitialComponents` contains the contour regions of the initial components. In contrast, if the initial components should be defined by the user, they can be directly passed in `InitialComponents`. However, instead of the contour regions for each initial component, its enclosing region must be passed in the tuple. The (contour) regions refer to the model image `ModelImage`. If the initial components have been obtained using `gen_initial_components`, the model image should be the same as in `gen_initial_components`. Please note that each initial component is part of at most one rigid model component. This is because during the

training initial components can be merged into rigid model components if required (see below). However, they cannot be split and distributed to several rigid model components.

`train_model_components` uses the following approach to perform the training: In the first step, the initial components are searched in all training images. In some cases, one initial component may be found in a training image more than once. Thus, in the second step, the resulting ambiguities are solved, i.e., the most probable pose of each initial component is found. Consequently, after solving the ambiguities, in all training images at most one pose of each initial component is available. In the next step the poses are analyzed and those initial components that do not show any relative movement are clustered to the final rigid model components. Finally, in the last step the relations between the model components are computed by analyzing their relative poses over the sequence of training images. The parameters that are associated with the mentioned steps are explained in the following.

The training is performed based on several training images, which are passed in `TrainingImages`. Each training image must show at most one instance of the compound object and should contain the full range of allowed relative movements of the model components. If, for example, the component model of an on/off switch should be trained, one training image that shows the switch turned off is sufficient if the switch in the model image is turned on, or vice versa.

The principle of the training is to find the initial components in all training images and to analyze their poses. For this, for each initial component a shape model is created (see `create_shape_model`), which is then used to determine the poses (position and orientation) of the initial components in the training images (see `find_shape_model`). Depending on the mode that is set by using `set_system('pregenerate_shape_models', ...)`, the shape model is either pregenerated completely or computed online during the search. The mode influences the computation time as well as the robustness of the training. Furthermore, it should be noted that if single-channel images are used in `ModelImage` as well as in `TrainingImages` the metric `'use_polarity'` is used internally for `create_shape_model`, while if multichannel images are used in either `ModelImage` or `TrainingImages` the metric `'ignore_color_polarity'` is used. Finally, it should be noted that while the number of channels in `ModelImage` and `TrainingImages` may be different, e.g., to facilitate model generation from synthetically generated images, the number of channels in all the images in `TrainingImages` must be identical. For further details see `create_shape_model`. The creation of the shape models can be influenced by choosing appropriate values for the parameters `ContrastLow`, `ContrastHigh`, and `MinSize`. These parameters have the same meaning as in `gen_initial_components` and can be automatically determined by passing `'auto'`: If both hysteresis threshold should be automatically determined, both `ContrastLow` and `ContrastHigh` must be set to `'auto'`. In contrast, if only one threshold value should be determined, `ContrastLow` must be set to `'auto'` while `ContrastHigh` must be set to an arbitrary value different from `'auto'`. If the initial components have been automatically created by `gen_initial_components`, the parameters `ContrastLow`, `ContrastHigh`, and `MinSize` should be set to the same values as in `gen_initial_components`.

To influence the search for the initial components, the parameters `MinScore`, `SearchRowTol`, `SearchColumnTol`, `SearchAngleTol`, and `TrainingEmphasis` can be set. The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the initial component in the training image. The larger `MinScore` is chosen, the faster the training is. If the initial components can be expected never to be occluded in the training images, `MinScore` may be set as high as 0.8 or even 0.9 (see `find_shape_model`).

By default, the components are searched only at points in which the component lies completely within the respective training image. This means that a component will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore`. This behavior can be changed with `set_system('border_shape_models', 'true')`, which will cause components that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the training will increase in this mode.

When dealing with a high number of initial components and many training images, the training may take a long time (up to several minutes). In order to speed up the training it is possible to restrict the search space for the single initial components in the training images. For this, the poses of the initial components in the model image are used as reference pose. The parameters `SearchRowTol` and `SearchColumnTol` specify the position tolerance region relative to the reference position in which the search is performed. Assume, for example, that the position of an initial component in the model image is (100,200) and `SearchRowTol` is set to 20 and `SearchColumnTol` is set to 10. Then, this initial component is searched in the training images only within the axis-aligned rectangle that is determined by the upper left corner (80,190) and the lower right corner (120,210). The same holds for the orientation angle range, which can be restricted by specifying the angle tolerance `SearchAngleTol` to

the angle range of $[-\text{SearchAngleTol}, +\text{SearchAngleTol}]$. Thus, it is possible to considerably reduce the computational effort during the training by an adequate acquisition of the training images. If one of the three parameters is set to -1 , no restriction of the search space is applied in the corresponding dimension.

The input parameters `ContrastLow`, `ContrastHigh`, `MinSize`, `MinScore`, `SearchRowTol`, `SearchColumnTol`, and `SearchAngleTol` must either contain one element, in which case the parameter is used for all initial components, or must contain the same number of elements as the initial components contained in `InitialComponents`, in which case each parameter element refers to the corresponding initial component in `InitialComponents`.

The parameter `TrainingEmphasis` offers another possibility to influence the computation time of the training and to simultaneously affect its robustness. If `TrainingEmphasis` is set to `'speed'`, on the one hand the training is comparatively fast, on the other hand it may happen in some cases that some initial components are not found in the training images or are found at a wrong pose. Consequently, this would lead to an incorrect computation of the rigid model components and their relations. The poses of the found initial components in the individual training images can be examined by using `get_training_components`. If erroneous matches occur the training should be restarted with `TrainingEmphasis` set to `'reliability'`. This results in a higher robustness at the cost of a longer computation time.

Furthermore, during the pose determination of the initial components ambiguities may occur if the initial components are rotationally symmetric or if several initial components are identical or at least similar to each other. To solve the ambiguities, the most probable pose is calculated for each initial component in each training image. For this, the individual ambiguous poses are evaluated. The pose of an initial component receives a good evaluation if the relative pose of the initial component with respect to the other initial components is similar to the corresponding relative pose in the model image. The method to evaluate this similarity can be chosen with `AmbiguityCriterion`. In almost all cases the best results are obtained with `'rigidity'`, which assumes the rigidity of the compound object. The more the rigidity of the compound object is violated by the pose of the initial component, the worse its evaluation is. In the case of `'distance'`, only the distance between the initial components is considered during the evaluation. Hence, the pose of the initial component receives a good evaluation if its distances to the other initial components is similar to the corresponding distances in the model image. Accordingly, when choosing `'orientation'`, only the relative orientation is considered during the evaluation. Finally, the simultaneous consideration of distance and orientation can be achieved by choosing `'distance_orientation'`. In contrast to `'rigidity'`, the relative pose of the initial components is not considered when using `'distance_orientation'`.

The process of solving the ambiguities can be further influenced by the parameter `MaxContourOverlap`. This parameter describes the extent by which the contours of two initial component matches may overlap each other. Let the letters 'I' and 'T', for example, be two initial components that should be searched in a training image that shows the string 'IT'. Then, the initial component 'T' should be found at its correct pose. In contrast, the initial component 'I' will be found at its correct pose ('I') but also at the pose of the 'T' because of the similarity of the two components. To discard the wrong match of the initial component 'I', an appropriate value for `MaxContourOverlap` can be chosen: If overlapping matches should be tolerated, `MaxContourOverlap` should be set to 1 . If overlapping matches should be completely avoided, `MaxContourOverlap` should be set to 0 . By choosing a value between 0 and 1 , the maximum percentage of overlapping contour pixels can be adjusted.

The decision which initial components can be clustered to rigid model components is made based on the poses of the initial components in the model image and in the training images. Two initial components are merged if they do not show any relative movement over all images. Assume that in the case of the above mentioned switch the training image would show the same switch state as the model image, the algorithm would merge the respective initial components because it assumes that the entire switch is one rigid model component. The extent by which initial components are merged can be influenced with the parameter `ClusterThreshold`. This cluster threshold is based on the probability that two initial components belong to the same rigid model component. Thus, `ClusterThreshold` describes the minimum probability which two initial components must have in order to be merged. Since the threshold is based on a probability value, it must lie in the interval between 0 and 1 . The greater the threshold is chosen, the smaller the number of initial components that are merged. If a threshold of 0 is chosen, all initial components are merged into one rigid component, while for a threshold of 1 no merging is performed and each initial component is adopted as one rigid model component.

The final rigid model components are returned in `ModelComponents`. Later, the index of a component region in `ModelComponents` is used to denote the model component. The poses of the components in the training images can be examined by using `get_training_components`.

After the determination of the model components their relative movements are analyzed by determining the movement of one component with respect to a second component for each pair of components. For this, the components are referred to their reference points. The reference point of a component is the center of gravity of its contour

region, which is returned in [ModelComponents](#). It can be calculated by calling [area_center](#). Finally, the relative movement is represented by the smallest enclosing rectangle of arbitrary orientation of the reference point movement and by the smallest enclosing angle interval of the relative orientation of the second component over all images. The determined relations can be inspected by using [get_component_relations](#).

Parameters

- ▷ **ModelImage** (input_object)(multichannel-)image $\leadsto$ object : byte / uint2
Input image from which the shape models of the initial components should be created.
- ▷ **InitialComponents** (input_object)region-array $\leadsto$ object
Contour regions or enclosing regions of the initial components.
- ▷ **TrainingImages** (input_object) (multichannel-)image(-array) $\leadsto$ object : byte / uint2
Training images that are used for training the model components.
- ▷ **ModelComponents** (output_object) region(-array) $\leadsto$ object
Contour regions of rigid model components.
- ▷ **ContrastLow** (input_control)integer(-array) $\leadsto$ integer / string
Lower hysteresis threshold for the contrast of the initial components in the image.
Default: 'auto'
Suggested values: ContrastLow $\in$ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
Restriction: ContrastLow > 0
- ▷ **ContrastHigh** (input_control) integer(-array) $\leadsto$ integer / string
Upper hysteresis threshold for the contrast of the initial components in the image.
Default: 'auto'
Suggested values: ContrastHigh $\in$ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
Restriction: ContrastHigh > 0 && ContrastHigh >= ContrastLow
- ▷ **MinSize** (input_control) integer(-array) $\leadsto$ integer / string
Minimum size of connected contour regions.
Default: 'auto'
Suggested values: MinSize $\in$ {'auto', 0, 5, 10, 20, 30, 40}
Restriction: MinSize >= 0
- ▷ **MinScore** (input_control) real(-array) $\leadsto$ real
Minimum score of the instances of the initial components to be found.
Default: 0.5
Suggested values: MinScore $\in$ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: 0 <= MinScore && MinScore <= 1
- ▷ **SearchRowTol** (input_control) integer(-array) $\leadsto$ integer
Search tolerance in row direction.
Default: -1
Suggested values: SearchRowTol $\in$ {0, 10, 20, 30, 50, 100}
Restriction: SearchRowTol == -1 || SearchColumnTol >= 0
- ▷ **SearchColumnTol** (input_control) integer(-array) $\leadsto$ integer
Search tolerance in column direction.
Default: -1
Suggested values: SearchColumnTol $\in$ {0, 10, 20, 30, 50, 100}
Restriction: SearchColumnTol == -1 || SearchColumnTol >= 0
- ▷ **SearchAngleTol** (input_control) angle.rad(-array) $\leadsto$ real
Angle search tolerance.
Default: -1
Suggested values: SearchAngleTol $\in$ {0.0, 0.17, 0.39, 0.78, 1.57}
Restriction: SearchAngleTol == -1 || SearchAngleTol >= 0
- ▷ **TrainingEmphasis** (input_control) string $\leadsto$ string
Decision whether the training emphasis should lie on a fast computation or on a high robustness.
Default: 'speed'
List of values: TrainingEmphasis $\in$ {'speed', 'reliability'}

- ▷ **AmbiguityCriterion** (input_control) string $\leadsto$ string
Criterion for solving ambiguous matches of the initial components in the training images.
Default: 'rigidity'
List of values: AmbiguityCriterion $\in$ {'distance', 'orientation', 'distance_orientation', 'rigidity'}
- ▷ **MaxContourOverlap** (input_control) real $\leadsto$ real
Maximum contour overlap of the found initial components in a training image.
Default: 0.2
Suggested values: MaxContourOverlap $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.05
Restriction: 0 <= MaxContourOverlap && MaxContourOverlap <= 1
- ▷ **ClusterThreshold** (input_control) real $\leadsto$ real
Threshold for clustering the initial components.
Default: 0.5
Suggested values: ClusterThreshold $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: 0 <= ClusterThreshold && ClusterThreshold <= 1
- ▷ **ComponentTrainingID** (output_control) component_training $\leadsto$ handle
Handle of the training result.

Example

```
* Get the model image.
read_image (ModelImage, 'model_image.tif')
* Define the regions for the initial components.
gen_rectangle2 (InitialComponentRegions, 212, 233, 0.62, 167, 29)
gen_rectangle2 (Rectangle2, 298, 363, 1.17, 162, 34)
gen_rectangle2 (Rectangle3, 63, 444, -0.26, 50, 27)
gen_rectangle2 (Rectangle4, 120, 473, 0, 33, 20)
concat_obj (InitialComponentRegions, Rectangle2, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle3, InitialComponentRegions)
concat_obj (InitialComponentRegions, Rectangle4, InitialComponentRegions)
* Get the training images.
gen_empty_obj (TrainingImages)
for i := 1 to 4 by 1
    read_image (TrainingImage, 'training_image-'+i+'.tif')
    concat_obj (TrainingImages, TrainingImage, TrainingImages)
endfor
* Extract the model components and train the relations.
train_model_components (ModelImage, InitialComponentRegions, \
    TrainingImages, ModelComponents, 22, 60, 30, 0.6, \
    0, 0, rad(60), 'speed', 'rigidity', 0.2, 0.4, \
    ComponentTrainingID)
```

Result

If the parameter values are correct, the operator `train_model_components` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Matching

```
write_component_model ( : : ComponentModelID, FileName : )
```

Write a component model to a file.

The operator `write_component_model` writes the component model [ComponentModelID](#) to the file [FileName](#). The model can be read again with [read_component_model](#). The default HALCON file extension for the component model is 'cbm'.

Parameters

- ▷ **ComponentModelID** (input_control) component_model $\leadsto$ handle
Handle of the component model.
- ▷ **FileName** (input_control) filename.write $\leadsto$ string
File name.
File extension: .cbm

Result

If the file name is valid (write permission), the operator `write_component_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

18.2 Correlation-Based

clear_ncc_model (: : ModelID :)

Free the memory of an NCC model.

The operator `clear_ncc_model` frees the memory of an NCC model that was created by `create_ncc_model`. After calling `clear_ncc_model`, the model can no longer be used. The handle `ModelID` becomes invalid.

Parameters

- ▷ **ModelID** (input_control) `ncc_model` $\leadsto$ *handle*
Handle of the model.

Result

If the handle of the model is valid, the operator `clear_ncc_model` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ModelID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

`find_ncc_models`

Module

Matching

create_ncc_model (Template : : NumLevels, AngleStart, AngleExtent,
AngleStep, Metric : ModelID)

Prepare an NCC model for matching.

The operator `create_ncc_model` prepares a template, which is passed in the image `Template`, as an NCC model used for matching using the normalized cross correlation (NCC). The ROI of the model is passed as the domain of `Template`.

The model is generated using multiple image pyramid levels at multiple rotations on each level and is stored in memory. The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_ncc_model`.

The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least eight) on the highest pyramid level. This can be checked using the domains of the output images of `gen_gauss_pyramid`. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_ncc_model` returns an error message. If `NumLevels` is set to `'auto'` or `0`, `create_ncc_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_ncc_model_params`. In rare cases, it might happen that `create_ncc_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` in `find_ncc_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_ncc_model` may increase. In these cases, the number of pyramid levels should be selected by inspecting the output of `gen_gauss_pyramid`. Here, `Mode = 'constant'` and `Scale = 0.5` should be used.

The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by `find_ncc_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_ncc_model`, this parameter specifies the accuracy that is achievable for the angles in `find_ncc_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not possess many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure a sampling of the range of possible rotations that is independent of the given `AngleStart`, the range of possible rotations is modified as follows: If there is no positive integer value n such that `AngleStart` plus n times `AngleStep` is exactly `0.0`, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

The model is pre-generated for the selected angle range and stored in memory. The memory required to store the model is proportional to the number of angle steps and the number of points in the model. Hence, if `AngleStep` is too small or `AngleExtent` too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either `AngleStep` must be enlarged or `AngleExtent` must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by `find_ncc_model`, `AngleStep  $\geq$  1` can be selected for models of a diameter smaller than about 200 pixels. If `AngleStep = 'auto'` or `0` is selected, `create_ncc_model` automatically determines a suitable angle step length based on the size of the model. The automatically computed angle step length can be queried using `get_ncc_model_params`.

The parameter `Metric` determines the conditions under which the model is recognized in the image. If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_ncc_model` will increase slightly in this case.

The center of gravity of the domain (region) of the model image `Template` is used as the origin (reference point) of the model. A different origin can be set with `set_ncc_model_origin`.

Parameters

- ▷ **Template** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.

- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the pattern.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in$ {6.29, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtent $\geq$ 0
- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ real / string
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0, 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep $\geq$ 0 && AngleStep $\leq$ pi / 16
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity'}
- ▷ **ModelID** (output_control) ncc_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_ncc_model` returns the value 2 (H_MSG_TRUE). If the parameter `NumLevels` are chosen such that the model contains too few points, the error 8506 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

deserialize_ncc_model (: : SerializedItemHandle : ModelID)

Deserialize an NCC model.

`deserialize_ncc_model` deserializes an NCC model, that was serialized by `serialize_ncc_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized NCC model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created NCC model with the handle `ModelID`.

Parameters

- ▷ **SerializedItemHandle** (input_control) serialized_item $\leadsto$ handle
Handle of the serialized item.
- ▷ **ModelID** (output_control) ncc_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `deserialize_ncc_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Matching

determine_ncc_model_params (Template : : NumLevels, AngleStart, AngleExtent, Metric, Parameters : ParameterName, ParameterValue)

Determine the parameters of an NCC model.

`determine_ncc_model_params` determines certain parameters of an NCC model automatically from the model image `Template`. The parameters to be determined can be specified with `Parameters`. `determine_ncc_model_params` can be used to determine the same parameters that are determined automatically when the respective parameter in `create_ncc_model` is set to 'auto': the number of pyramid levels (`Parameters = 'num_levels'`) and/or the angle step length (`Parameters = 'angle_step'`). By passing a tuple of the above values in `Parameters`, an arbitrary combination of these parameters can be determined. If all of the above parameters should be determined, the value 'all' can be passed.

`determine_ncc_model_params` is mainly useful to determine the above parameters before creating the model, e.g., in an interactive system, which makes suggestions for these parameters to the user, but enables the user to modify the suggested values.

The automatically determined parameters are returned as a name-value pair in `ParameterName` and `ParameterValue`. The parameter names in `ParameterName` are identical to the names in `Parameters`, where, of course, the value 'all' is replaced by the actual parameter names.

The input parameters (`NumLevels`, `AngleStart`, `AngleExtent`, and `Metric`) have the same meaning as in `create_ncc_model`. The description of these parameters can be looked up with this operator. These parameters are used by `determine_ncc_model_params` to calculate the parameters to be determined in the same manner as in `create_ncc_model`.

Note that in `determine_ncc_model_params` the input parameter `NumLevels` can also be determined automatically. If this parameter should not be determined automatically, i.e., the name is not passed in `Parameters`, the parameter must contain a valid value and must not be set to 'auto'. In contrast, if the maximum number of pyramid levels is to be determined automatically, i.e., `Parameters` contains the value 'num_levels', you can let HALCON determine a suitable value and at the same time specify an upper boundary:

If the maximum number of pyramid levels should be specified in advance, the input parameter `NumLevels` can be set to the particular value. If in this case `Parameters` contains the value 'num_levels', the computed number of pyramid levels is at most `NumLevels`. If `NumLevels` is set to 'auto' or 0, the number of pyramid levels is determined without restrictions as large as possible.

Parameters

- ▷ **Template** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the model.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in$ {6.29, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtent $\geq$ 0
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity'}
- ▷ **Parameters** (input_control) string(-array) $\leadsto$ string
Parameters to be determined automatically.
Default: 'all'
List of values: Parameters $\in$ {'all', 'num_levels', 'angle_step'}
- ▷ **ParameterName** (output_control) string-array $\leadsto$ string
Name of the automatically determined parameter.
- ▷ **ParameterValue** (output_control) number-array $\leadsto$ real / integer
Value of the automatically determined parameter.

Result

If the parameters are valid, the operator `determine_ncc_model_params` returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

[find_ncc_model](#)

Module

Matching

```
find_ncc_model ( Image : : ModelID, AngleStart, AngleExtent,
                MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels : Row,
                Column, Angle, Score )
```

Find the best matches of an NCC model in an image.

The operator `find_ncc_model` finds the best `NumMatches` instances of the NCC model `ModelID` in the input image `Image`. The model must have been created previously by calling `create_ncc_model` or `read_ncc_model`.

The position and rotation of the found instances of the model is returned in `Row`, `Column`, and `Angle`. Additionally, the score of each found instance is returned in `Score`.

If NCC finds no suitable match or the matching scores are too low, the search should be performed using a different matching method (see, e.g., "Solution Guide II-B - Matching").

Input parameters in detail

Image and its domain: The domain of the image `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. A different origin set with `set_ncc_model_origin` is not taken into account here. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that rounding effects can cause matches to lie up to $0.5 * 2^{\text{NumLevels}-1}$ pixels outside the image.

AngleStart and AngleExtent: The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with `create_ncc_model`.

MinScore: The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is.

NumMatches: The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. If the model has repeating structures it may happen that multiple instances with identical rotations are found at similar positions in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap` = 0, the found instances may not overlap at all, while for `MaxOverlap` = 1 all instances are returned.

SubPixel: The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to 'false', the model's pose is only determined with pixel accuracy and the angle resolution that was specified with `create_ncc_model`. If `SubPixel` is set to 'true', the position as well as the rotation are determined with subpixel accuracy. In this mode, the model's pose is interpolated from the score function. This mode costs almost no computation time and achieves a high accuracy. Hence, `SubPixel` should usually be set to 'true'. Note that the subpixel accurate determination of the model's pose is only possible if the found instance lies at least 2 pixels away from the image border of the lowest used pyramid level. If the instance lies closer to the image border, its pose is only determined with pixel accuracy and the angle resolution that was specified with `create_ncc_model`, even if `SubPixel` is set to 'true'.

NumLevels: The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the NCC model was created with `create_ncc_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_ncc_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_ncc_model` may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_ncc_model_params` and then use a slightly lower value in `find_ncc_model`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a

reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

Output parameters in detail

Row, Column and Angle: The position and rotation of the found instances of the model is returned in [Row](#), [Column](#), and [Angle](#). The coordinates [Row](#) and [Column](#) are related to the position of the origin of the model in the search image. However, [Row](#) and [Column](#) do not exactly correspond to this position. Instead, `find_ncc_model` returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model. (This has to do with the way HALCON transforms iconic objects, see [affine_trans_pixel](#)). The example below shows how to create the transformation matrix for alignment and how to calculate the exact coordinates of the found matches.

By default, the origin is the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. A different origin can be set with `set_ncc_model_origin`.

Score: Additionally, the score of each found instance is returned in [Score](#). The score is the normalized cross correlation of the template $t(r, c)$ and the image $i(r, c)$:

$$\text{ncc}(r, c) = \frac{1}{n} \sum_{(u,v) \in R} \frac{t(u, v) - m_t}{\sqrt{s_t^2}} \cdot \frac{i(r + u, c + v) - m_i(r, c)}{\sqrt{s_i^2(r, c)}}$$

Here, n denotes the number of points in the template, R denotes the domain (ROI) of the template, m_t is the mean gray value of the template

$$m_t = \frac{1}{n} \sum_{(u,v) \in R} t(u, v)$$

s_t^2 is the variance of the gray values of the template

$$s_t^2 = \frac{1}{n} \sum_{(u,v) \in R} (t(u, v) - m_t)^2$$

$m_i(r, c)$ is the mean gray value of the image at position (r, c) over all points of the template (i.e., the template points are shifted by (r, c))

$$m_i(r, c) = \frac{1}{n} \sum_{(u,v) \in R} i(r + u, c + v)$$

and $s_i^2(r, c)$ is the variance of the gray values of the image at position (r, c) over all points of the template

$$s_i^2(r, c) = \frac{1}{n} \sum_{(u,v) \in R} (i(r + u, c + v) - m_i(r, c))^2$$

The NCC measures how well the template and image correspond at a particular point (r, c) . It assumes values between -1 and 1 . The larger the absolute value of the correlation, the larger the degree of correspondence between the template and image. A value of 1 means that the gray values in the image are a linear transformation of the gray values in the template:

$$i(r + u, c + v) = at(u, v) + b$$

where $a > 0$. Similarly, a value of -1 means that the gray values in the image are a linear transformation of the gray values in the template with $a < 0$. Hence, in this case the template occurs with a reversed polarity in the image. Because of the above property, the NCC is invariant to linear illumination changes.

The NCC as defined above is used if the NCC model has been created with `Metric = 'use_polarity'`. If the model has been created with `Metric = 'ignore_global_polarity'`, the absolute value of $\text{ncc}(r, c)$ is used as the score.

Specifying a timeout

Using the operator `set_ncc_model_param` you can specify a 'timeout' for `find_ncc_model`. If `find_ncc_model` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

Visualization of the results

To display the results found by correlation-based matching, we highly recommend the usage of the procedure `dev_display_ncc_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter [Transformations / 2D Transformations](#).

Attention

`find_ncc_model` can be partially executed on OpenCL devices that support the `cl_khr_global_int32_base_atomics` OpenCL extension. Only the initial search for the model in the topmost pyramid level is done on the OpenCL device, while the tracking of matches is done on the host CPU. If the domain of the image to search in is substantially smaller than the size of the image, use `crop_domain` to reduce the amount of data that needs to be copied from the OpenCL device to the host CPU. Note that `find_ncc_model` using OpenCL may run either substantially faster or slower depending on a wide number of factors, so the only way to tell if using OpenCL is beneficial is by testing with images from the actual application.

Furthermore, note that the internally used memory increases with the number of used threads.

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Input image in which the model should be found.
- ▷ **ModelID** (input_control) ncc_model $\leadsto$ handle
Handle of the model.
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the model.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
- ▷ **MinScore** (input_control) real $\leadsto$ real
Minimum score of the instances of the model to be found.
Default: 0.8
Suggested values: MinScore $\in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control) integer $\leadsto$ integer
Number of instances of the model to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in \{0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **MaxOverlap** (input_control) real $\leadsto$ real
Maximum overlap of the instances of the model to be found.
Default: 0.5
Suggested values: MaxOverlap $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **SubPixel** (input_control) string $\leadsto$ string
Subpixel accuracy.
Default: 'true'
List of values: SubPixel $\in \{'false', 'true'\}$

- ▷ **NumLevels** (input_control) integer(-array) $\leadsto$ integer
 Number of pyramid levels used in the matching (and lowest pyramid level to use if `|NumLevels| = 2`).
Default: 0
List of values: NumLevels $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **Row** (output_control) point.y-array $\leadsto$ real
 Row coordinate of the found instances of the model.
- ▷ **Column** (output_control) point.x-array $\leadsto$ real
 Column coordinate of the found instances of the model.
- ▷ **Angle** (output_control) angle.rad-array $\leadsto$ real
 Rotation angle of the found instances of the model.
- ▷ **Score** (output_control) real-array $\leadsto$ real
 Score of the found instances of the model.

Example

```
create_ncc_model (TemplateImage, 'auto', rad(-45), rad(90), 'auto', \
                  'use_polarity', ModelID)
find_ncc_model (SearchImage, ModelID, rad(-45), rad(90), 0.7, 1, \
               0.5, 'true', 0, Row, Column, Angle, Score)
* Create transformation matrix
vector_angle_to_rigid (0, 0, 0, Row, Column, Angle, HomMat2D)
* Calculate true position of the model origin in the search image
affine_trans_pixel (HomMat2D, 0, 0, RowObject, ColumnObject)
* display the results
dev_display_ncc_matching_results (ModelID, 'red', Row, Column, \
                                 Angle, 0)
```

Result

If the parameter values are correct, the operator `find_ncc_model` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

`create_ncc_model`, `read_ncc_model`, `set_ncc_model_origin`

Possible Successors

`clear_ncc_model`

Alternatives

`find_generic_shape_model`

Module

Matching

```
find_ncc_models ( Image : : ModelIDs, AngleStart, AngleExtent,
                  MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels : Row,
                  Column, Angle, Score, Model )
```

Find the best matches of multiple NCC models.

The operator `find_ncc_models` finds the best `NumMatches` instances of the NCC models that are passed in the tuple `ModelIDs` in the input `Image`. The models must have been created previously by calling

`create_ncc_model` or `read_ncc_model`. In contrast to `find_ncc_model`, multiple models can be searched in the same image in one call.

If NCC finds no suitable match or the matching scores are too low, the search should be performed using a different matching method (see, e.g., "Solution Guide II-B - Matching").

Characteristics of the parameter semantics

Compared to `find_ncc_model`, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or they must contain the same number of elements as `ModelIDs`, in which case each parameter element refers to the corresponding element in `ModelIDs`. (`NumLevels` may also contain either two or twice the number of elements as `ModelIDs`). More details can be found below in the sections containing information for the respective parameters. Note that a call to `find_ncc_models` with multiple values for `ModelIDs`, `NumMatches` and `MaxOverlap` has the same effect as multiple independent calls to `find_ncc_model` with the respective parameters. However, a single call to `find_ncc_models` is considerably more efficient.

Input parameters in detail

Image and its domain: The domain of the image `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. A different origin set with `set_ncc_model_origin` is not taken into account. The model has to lie completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that rounding effects can cause matches to lie up to $0.5 * 2^{\text{NumLevels}-1}$ pixels outside the image.

The input `Image` can contain a single image object or an image object array containing multiple image objects. If `Image` contains a single image object, its domain is used as the region of interest for all models in `ModelIDs`. If `Image` contains multiple image objects, each domain is used as the region of interest for the corresponding model in `ModelIDs`. In this case, the images have to be identical except for their domains, i.e., `Image` cannot be constructed in an arbitrary manner using `concat_obj`, but must be created from the same image using `add_channels` or equivalent calls. If this is not the case, an error message is returned.

AngleStart and AngleExtent: The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with `create_ncc_model`.

Furthermore, it should be noted that in some cases instances with a rotation that is slightly outside the specified range of rotations are found. This may happen if the specified range of rotations is smaller than the range given when the model was created.

MinScore: The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is. If the model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see `NumLevels`), it might happen that instances with a score slightly below `MinScore` are found.

NumMatches: The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

If `NumMatches` contains one element, `find_ncc_models` returns the best `NumMatches` instances of the model irrespective of the type of the model. If, for example, two models are passed in `ModelIDs` and `NumMatches = 2` is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, `NumMatches` contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in `NumMatches`. If, for example, `NumMatches = [1, 1]` is selected, one instance of the first model and one instance of the second model is returned.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap`, only

the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap` = 0, the found instances may not overlap at all, while for `MaxOverlap` = 1 all instances are returned.

If a single value is passed in `MaxOverlap`, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in `MaxOverlap`, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

SubPixel: The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to `'false'` the model's pose is only determined with pixel accuracy and the angle resolution that was specified with `create_ncc_model`. If `SubPixel` is set to `'true'`, the position as well as the rotation are determined with subpixel accuracy. In this mode, the model's pose is interpolated from the score function.

NumLevels: The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the NCC model was created with `create_ncc_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_ncc_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_ncc_model` may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_ncc_model_params` and then use a slightly lower value in `find_ncc_models`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of `[4,2]` for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, `NumLevels` must contain twice the number of elements as `ModelIDs`. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in `NumLevels`. If, for example, two models are specified in `ModelIDs`, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model, `NumLevels` = `[5, 2, 4, 1]` must be selected. If exactly two models are specified in `ModelIDs`, a special case occurs. If in this case the lowest pyramid level is to be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in `NumLevels` is interpreted as the explicit specification of the number of pyramid levels for the two models.

Output parameters in detail

Row, Column and Angle: The position and rotation of the found instances of the model is returned in `Row`, `Column`, and `Angle`. The coordinates `Row` and `Column` are the coordinates of the origin of the NCC model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. A different origin can be set with `set_ncc_model_origin`.

Note that the coordinates `Row` and `Column` do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for `find_ncc_model` shows how to create this matrix and use it to display the model at the found position in the search image and to calculate the exact coordinates.

Note also that for visualizing the model at the found position, also the procedure `dev_display_ncc_matching_results` can be used.

Score: Additionally, the score of each found instance is returned in `Score`.

Model: The type of the found instances of the models is returned in `Model`. The elements of `Model` are indices into the tuple `ModelIDs`, i.e., they can contain values from 0 to $|\text{ModelIDs}| - 1$. Hence, a value of 0 in an element of `Model` corresponds to an instance of the first model in `ModelIDs`.

Specifying a timeout

Using the operator `set_ncc_model_param` you can specify a 'timeout' for `find_ncc_models`. If the NCC models referenced by `ModelIDs` hold different values for 'timeout', `find_ncc_models` uses the smallest one. If `find_ncc_models` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

Visualization of the results

To display the results found by correlation-based matching, we highly recommend the usage of the procedure `dev_display_ncc_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter [Transformations / 2D Transformations](#).

Attention

Note that the internally used memory increases with the number of used threads.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / uint2
Input image in which the model should be found.
- ▷ **ModelIDs** (input_control) ncc_model(-array) $\leadsto$ *handle*
Handle of the models.
- ▷ **AngleStart** (input_control) angle.rad(-array) $\leadsto$ *real*
Smallest rotation of the models.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad(-array) $\leadsto$ *real*
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
- ▷ **MinScore** (input_control) real(-array) $\leadsto$ *real*
Minimum score of the instances of the models to be found.
Default: 0.8
Suggested values: MinScore $\in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control) integer(-array) $\leadsto$ *integer*
Number of instances of the models to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in \{0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **MaxOverlap** (input_control) real(-array) $\leadsto$ *real*
Maximum overlap of the instances of the models to be found.
Default: 0.5
Suggested values: MaxOverlap $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **SubPixel** (input_control) string(-array) $\leadsto$ *string*
Subpixel accuracy if not equal to 'none'.
Default: 'true'
List of values: SubPixel $\in \{'false', 'true'\}$

- ▷ **NumLevels** (input_control) integer(-array) $\leadsto$ integer
Number of pyramid levels used in the matching (and lowest pyramid level to use if `|NumLevels| = 2`).
Default: 0
List of values: NumLevels $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **Row** (output_control) point.y-array $\leadsto$ real
Row coordinate of the found instances of the models.
- ▷ **Column** (output_control) point.x-array $\leadsto$ real
Column coordinate of the found instances of the models.
- ▷ **Angle** (output_control) angle.rad-array $\leadsto$ real
Rotation angle of the found instances of the models.
- ▷ **Score** (output_control) real-array $\leadsto$ real
Score of the found instances of the models.
- ▷ **Model** (output_control) integer-array $\leadsto$ integer
Index of the found instances of the models.

Example

```
read_image (Image, 'pcb_focus/pcb_focus_telecentric_061')
gen_rectangle1 (ROI_0, 236, 241, 313, 321)
gen_circle (ROI_1, 281, 653, 41)
reduce_domain (Image, ROI_0, ImageReduced1)
reduce_domain (Image, ROI_1, ImageReduced2)
create_ncc_model (ImageReduced1, 'auto', rad(-45), rad(90), 'auto', \
                  'use_polarity', ModelID1)
create_ncc_model (ImageReduced2, 'auto', rad(-45), rad(90), 'auto', \
                  'use_polarity', ModelID2)
ModelIDs:=[ModelID1, ModelID2]
find_ncc_models (Image, ModelIDs, rad(-45), rad(90), 0.7, [1,1], 0.5, \
                 'true', 0, Row, Column, Angle, Score, Model)
dev_display_ncc_matching_results (ModelIDs, 'red', Row, Column, \
                                  Angle, Model)
```

Result

If the parameter values are correct, the operator `find_ncc_models` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Matching

get_ncc_model_origin (: : ModelID : Row, Column)

Return the origin (reference point) of an NCC model.

The operator `get_ncc_model_origin` returns the origin (reference point) of the NCC model `ModelID`. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

Parameters

- ▷ **ModelID** (input_control) `ncc_model` $\rightsquigarrow$ *handle*
Handle of the model.
- ▷ **Row** (output_control) `point.y` $\rightsquigarrow$ *real*
Row coordinate of the origin of the NCC model.
- ▷ **Column** (output_control) `point.x` $\rightsquigarrow$ *real*
Column coordinate of the origin of the NCC model.

Result

If the handle of the model is valid, the operator `get_ncc_model_origin` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
get_ncc_model_params ( : : ModelID : NumLevels, AngleStart,
                        AngleExtent, AngleStep, Metric )
```

Return the parameters of an NCC model.

The operator `get_ncc_model_params` returns the parameters of the NCC model `ModelID` that were used to create it using `create_ncc_model`. In particular, this output can be used to check the parameters `NumLevels` and `AngleStep` if they were determined automatically during the model creation with `create_ncc_model`. Furthermore, this output can be used to check the parameters if the model was read with `read_ncc_model`.

Parameters

- ▷ **ModelID** (input_control) `ncc_model` $\rightsquigarrow$ *handle*
Handle of the model.
- ▷ **NumLevels** (output_control) `integer` $\rightsquigarrow$ *integer*
Number of pyramid levels.
- ▷ **AngleStart** (output_control) `angle.rad` $\rightsquigarrow$ *real*
Smallest rotation of the pattern.
- ▷ **AngleExtent** (output_control) `angle.rad` $\rightsquigarrow$ *real*
Extent of the rotation angles.
Assertion: `AngleExtent >= 0`
- ▷ **AngleStep** (output_control) `angle.rad` $\rightsquigarrow$ *real*
Step length of the angles (resolution).
Assertion: `AngleStep >= 0`

▷ **Metric** (output_control) string $\leadsto$ string
Match metric.

Result

If the handle of the model is valid, the operator `get_ncc_model_params` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`find_ncc_model`

Module

Matching

get_ncc_model_region (: ModelRegion : ModelID :)

Return the region used to create an NCC model.

The operator `get_ncc_model_region` returns the region used to create the NCC model `ModelID` in `ModelRegion`. This region can be used, for example, to visualize the found instances of the model in an image. It should be noted that the position of `ModelRegion` is normalized such that the reference point of the model (see `set_ncc_model_origin`) lies at the pixel position (0, 0). Hence, the region simply needs to be translated to the found position in the image (and possibly rotated around this point). `get_ncc_model_region` ignores the value of the system parameter '`clip_region`'.

Parameters

- ▷ **ModelRegion** (output_object) region $\leadsto$ object
Model region of the NCC model.
- ▷ **ModelID** (input_control) ncc_model $\leadsto$ handle
Handle of the model.

Result

If the handle of the NCC model is valid, the operator `get_ncc_model_region` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_ncc_model`

Module

Matching

read_ncc_model (: : FileName : ModelID)

Read an NCC model from a file.

The operator `read_ncc_model` reads an NCC model, which has been written with `write_ncc_model`, from the file `FileName`. The default HALCON file extension for the NCC model is 'ncm'.

Parameters

- ▷ **FileName** (input_control) filename.read $\leadsto$ string
File name.
File extension: .ncm
- ▷ **ModelID** (output_control) ncc_model $\leadsto$ handle
Handle of the model.

Result

If the file name is valid, the operator `read_ncc_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`find_ncc_model`, `find_ncc_models`

See also

`create_ncc_model`, `clear_ncc_model`

Module

Matching

serialize_ncc_model (: : ModelID : SerializedItemHandle)

Serialize an NCC model.

`serialize_ncc_model` serializes the data of an NCC model (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_ncc_model` is converted to a serialized item. The NCC model is defined by the handle `ModelID`. The serialized NCC model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_ncc_model`.

Parameters

- ▷ **ModelID** (input_control) ncc_model $\leadsto$ handle
Handle of the model.
- ▷ **SerializedItemHandle** (output_control) serialized_item $\leadsto$ handle
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_ncc_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_ncc_model`

Possible Successors

Module

Matching

set_ncc_model_origin (: : ModelID, Row, Column :)
--

Set the origin (reference point) of an NCC model.

The operator `set_ncc_model_origin` sets the origin (reference point) of the NCC model `ModelID` to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the NCC model with `create_ncc_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

Parameters

- ▷ **ModelID** (input_control) ncc_model $\leadsto$ handle
Handle of the model.
- ▷ **Row** (input_control) point.y $\leadsto$ real
Row coordinate of the origin of the NCC model.
- ▷ **Column** (input_control) point.x $\leadsto$ real
Column coordinate of the origin of the NCC model.

Result

If the handle of the model is valid, the operator `set_ncc_model_origin` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ModelID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_ncc_model`, `read_ncc_model`

Possible Successors

`area_center`

Module

Matching

set_ncc_model_param (: : ModelID, GenParamName, GenParamValue :)
--

Set selected parameters of the NCC model.

The operator `set_ncc_model_param` sets the selected parameters `GenParamName` in the NCC model `ModelID`. The following parameters can be modified:

'timeout'

Sets the maximum runtime of the operators used to find the NCC model `ModelID` (using `find_ncc_model`). This is especially useful in cases where a maximum cycle time has to be ensured. The *'timeout'* must be given in

milliseconds. The temporal accuracy depends on several factors including the size of the model, the speed of your computer, and the *'timer_mode'* set via [set_system](#). Be aware that the runtime of the search increases by up to 10 percent with activated timeout. To disable the timeout you can either use a negative value or *'false'*.

Parameters

- ▷ **ModelID** (input_control) ncc_model $\leadsto$ *handle*
Handle of the model.
- ▷ **GenParamName** (input_control) attribute.name-array $\leadsto$ *string*
Parameter names.
List of values: GenParamName $\in$ { 'timeout' }
- ▷ **GenParamValue** (input_control) attribute.value-array $\leadsto$ *real / integer / string*
Parameter values.

Result

If the parameters are valid, the operator `set_ncc_model_param` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

write_ncc_model (: : ModelID, FileName :)

Write an NCC model to a file.

The operator `write_ncc_model` writes an NCC model to the file [FileName](#). The model can be read again with [read_ncc_model](#). The default HALCON file extension for the NCC model is 'ncm'.

Parameters

- ▷ **ModelID** (input_control) ncc_model $\leadsto$ *handle*
Handle of the model.
- ▷ **FileName** (input_control) filename.write $\leadsto$ *string*
File name.
File extension: .ncm

Result

If the file name is valid (write permission), the operator `write_ncc_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

18.3 Deep Counting

This chapter explains how to use Deep Counting.

Deep Counting is used to find objects in images and returns the number of objects.

A possible example for a Deep Counting application: Objects in an image are counted and the object quantity is returned.

Deep Counting uses user-defined templates to prepare a Deep Counting model. This model can be used to count objects that resemble the templates.

The general workflow is described in the following section.

General Workflow

This paragraph describes how to obtain the number from objects of a kind in images using a Deep Counting model. An application scenario can be seen in the HDevelop example `deep_counting_workflow.hdev`

1. Create a Deep Counting model by using
 - `create_deep_counting_model`.
2. Query the available DL devices for inference by using
 - `query_available_dl_devices`.
3. Set the model parameters, the used devices or augmentation parameters for the templates using
 - `set_deep_counting_model_param`.
4. Draw templates for the preparation of the model. This can be done using the procedure
 - `draw_deep_counting_templates`.

The drawn templates are needed for the operator `prepare_deep_counting_model`.

5. Prepare the model for the inference using
 - `prepare_deep_counting_model`.

Note that when changing parameters that influence the template creation, or when other templates should be used, `prepare_deep_counting_model` must be called again, before the model can be applied with `apply_deep_counting_model`.

6. Apply the model using the operator
 - `apply_deep_counting_model`.

The result will be saved in `DeepCountingResult`.

7. Visualize the Deep Counting results from `DeepCountingResult` using the procedure

- `dev_display_deep_counting_results`.

```
apply_deep_counting_model ( Image : : DeepCountingHandle : Count,
                             DeepCountingResult )
```

Apply a Deep Counting model on a set of images for inference.

`apply_deep_counting_model` applies the Deep Counting model given by `DeepCountingHandle` on the tuple of input images `Image`. A tuple with the number of found instances per input image is returned in `Count`. Additional information about the counted instances is returned in `DeepCountingResult`, which contains a tuple of dictionaries, again one per input image. Note that templates of the objects to be counted must be set beforehand using `prepare_deep_counting_model`. Note that the inference time of `apply_deep_counting_model` depends on the number of defined templates in `prepare_deep_counting_model`.

Please see the chapter [Matching / Deep Counting](#) for further information.

The procedure `dev_display_deep_count_results` can be used to visualize the detected instances.

The settings `'min_score'` and `'max_overlap'` can be used to set the minimum similarity of the instances to the templates as well as the allowed overlap of instances. Details can be found in `get_deep_counting_model_param`.

The dictionary returned in `DeepCountingResult` contains additional information about the detected and counted object instances. It contains the following keys, where each key contains a tuple of values, one for each detection. If no instances were detected, i.e. the count is 0, those tuples are empty.

`'area':`

Approximate area of the detected templates in pixels.

`'row', 'column':`

Approximate location in row and column coordinates of the instances in the input image.

`'score':`

Similarity score of the detected instances, i.e., their approximate similarity with the most similar template provided to `prepare_deep_counting_model`.

`'template_index':`

Index of the template with the highest similarity to the detected instance. This can be used to find out which templates were counted.

`'angle', 'scale':`

The angle and scale of the template with the highest similarity to the detected instance. If rotational or scale augmentations were enabled during the call of `prepare_deep_counting_model`, these values can be used to find out which rotation angle and scale creates a template that is most similar to the detected instance.

Attention

System requirements: To run this operator on GPU (see `get_deep_counting_model_param`), cuDNN and cuBLAS are required. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods". Alternatively, this operator can also be run on CPU.

Parameters

- ▷ **Image** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / real
Input image.
- ▷ **DeepCountingHandle** (input_control) `deep_counting` $\leadsto$ *handle*
Handle of the Deep Counting model.
- ▷ **Count** (output_control) integer(-array) $\leadsto$ *integer*
Number of counted objects.
- ▷ **DeepCountingResult** (output_control) dict(-array) $\leadsto$ *handle*
Tuple of result dictionaries.

Result

If the parameters are valid, the operator `apply_deep_counting_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

`prepare_deep_counting_model`

Module

Matching

create_deep_counting_model (: : GenParamName, GenParamValue : DeepCountingHandle)

Create a Deep Counting model for counting objects.

`create_deep_counting_model` creates a Deep Counting model and returns its handle in `DeepCountingHandle`.

Internally `create_deep_counting_model` builds a backbone based on the pretrained network '`pre-trained_dl_classifier_resnet50.hdl`', which must be available. See `read_dl_model` for details on where the file is searched.

Additional parameters of the Deep Counting model can be set using the generic parameters `GenParamName` and `GenParamValue`. See `get_deep_counting_model_param` for a list of parameters and their possible values. The parameters can either be set during model creation, or later using `set_deep_counting_model_param`.

Note that before using the returned Deep Counting model with `apply_deep_counting_model`, templates must be stored in the model using `prepare_deep_counting_model`.

Parameters

- ▷ **GenParamName** (input_control)attribute.name(-array) $\leadsto$ *string*
Parameter names.
Default: []
List of values: `GenParamName` $\in$ { 'angle_start', 'angle_end', 'angle_step', 'device', 'max_overlap', 'min_score', 'scale_min', 'scale_max', 'scale_step' }
- ▷ **GenParamValue** (input_control)attribute.value(-array) $\leadsto$ *real / integer / string*
Parameter values.
Default: []
- ▷ **DeepCountingHandle** (output_control)deep_counting $\leadsto$ *handle*
Deep Counting model for counting objects.

Result

If the parameters are valid, the operator `create_deep_counting_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

get_deep_counting_model_param (: : DeepCountingHandle, GenParamName : GenParamValue)
--

Return the parameters of a Deep Counting model.

The operator `get_deep_counting_model_param` returns the parameter values of `GenParamName` for the Deep Counting model `DeepCountingHandle` in `GenParamValue`.

Note that when changing parameters that influence the template creation, `prepare_deep_counting_model` must be called again before the model can be applied with `apply_deep_counting_model`. The following table gives an overview, which parameters can be set using `set_deep_counting_model_param` or `create_deep_counting_model` (set), which can be retrieved using `get_deep_counting_model_param` (get), and which require re-running `prepare_deep_counting_model` after changing them (prepare).

GenParamName	set	get	Requires prepare
'angle_start'	x	x	x
'angle_step'	x	x	x
'angle_end'	x	x	x
'backbone_model'	x	x	x
'device'	x	x	x
'max_overlap'	x	x	
'min_score'	x	x	
'scale_max'	x	x	x
'scale_min'	x	x	x
'scale_step'	x	x	x

In the following the parameters are described:

'angle_start', 'angle_step', 'angle_end':

Control the rotational augmentation. Templates passed to `prepare_deep_counting_model` are rotated from `'angle_start'` to `'angle_end'` in steps of `'angle_step'`. This allows `apply_deep_counting_model` to better find rotated instances of the templates.

The angles must be passed in radians.

Suggested values: 0, -6.28, -3.14, 3.14, 6.28

Default: `'angle_start' = 0, 'angle_end' = 0, 'angle_step' = 'rad(30)'`

Restriction:

$-2\pi \leq 'angle_start' \leq 'angle_end' \leq 2\pi, 'angle_step' > 0$

'backbone_model':

The backbone used for the detection of the templates. The backbone is automatically created by [create_deep_counting_model](#). It can be obtained and written back in order to, for example, optimize it using [optimize_dl_model_for_inference](#).

Note that the Deep Counting model will automatically set the input size of the backbone according to the template and image sizes. It has therefore no effect to change the backbone's input size, and it is not recommended to do so. Also note that the backbone can not be used for any other deep learning methods besides Deep Counting.

'device':

Handle of the device on which the backbone will be executed.

If the backbone was already optimized for a device, setting *'device'* might not be necessary anymore, see [optimize_dl_model_for_inference](#) for details.

To get a tuple of handles of all available potentially deep-learning capable hardware devices use [query_available_dl_devices](#).

Default: Handle of the default device, thus the GPU with index 0. If not available, this is an empty tuple.

'max_overlap':

The maximum allowed intersection over union (IoU) for two detected templates during counting. When two templates have an IoU higher than *'max_overlap'*, the one with lower confidence value gets suppressed. When set to 0, no overlap at all is allowed. We refer to the chapter [Deep Learning / Object Detection and Instance Segmentation](#) for further explanations of the IoU.

Suggested values: 0.3, 0.5, 0.7, 1.0

Default: *'max_overlap'* = 0.5

Restriction: $0 \leq \text{'max_overlap'} \leq 1$

'min_score':

This parameter determines the minimum similarity of detected instances to the original templates. In other words, [apply_deep_counting_model](#) ignores all detected instances with a similarity smaller than this value. The similarity computed by the Deep Counting model lies between 0 and 1, where 0 means no similarity and 1 is a very high similarity.

Suggested values: 0.2, 0.3, 0.4, 0.5

Default: *'min_score'* = 0.4

Restriction: $0 < \text{'min_score'} \leq 1$

'scale_min', 'scale_step', 'scale_max':

Control the scale augmentation. Templates passed to [prepare_deep_counting_model](#) are scaled from *'scale_min'* to *'scale_max'* in steps of *'scale_step'*. This allows [apply_deep_counting_model](#) to better find scaled instances of the templates.

Suggested values: 0.9, 1.0, 1.1

Default: *'scale_min'* = 1.0, *'scale_max'* = 1.0, *'scale_step'* = 0.1

Restriction: $0 < \text{'scale_min'} \leq \text{'scale_max'}$, *'scale_step'* > 0

Parameters

- ▷ **DeepCountingHandle** (input_control) deep_counting $\leadsto$ handle
Handle of the Deep Counting model.
- ▷ **GenParamName** (input_control) attribute.name $\leadsto$ string
Name of the generic parameter.
Default: *'angle_start'*
List of values: GenParamName $\in$ {*'angle_start'*, *'angle_end'*, *'angle_step'*, *'backbone_model'*, *'device'*, *'max_overlap'*, *'min_score'*, *'scale_min'*, *'scale_max'*, *'scale_step'*}
- ▷ **GenParamValue** (output_control) attribute.name $\leadsto$ real / string / integer
Value of the generic parameter.

Result

If the handle of the model is valid, the operator `get_deep_counting_model_param` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

prepare_deep_counting_model (Templates : : DeepCountingHandle :)

Set templates of a Deep Counting model.

`prepare_deep_counting_model` sets the templates of the objects that should be counted by the Deep Counting model `DeepCountingHandle`. When applying the Deep Counting model using `apply_deep_counting_model`, objects in the search images that are similar to the provided templates are detected and counted. Note that this operator overwrites any previously set templates.

To also count scaled and rotated variants of the provided templates, an automatic augmentation of the templates can be enabled by setting the parameters `'angle_start'`, `'angle_end'`, `'angle_step'`, `'scale_min'`, `'scale_max'`, and `'scale_step'` using `create_deep_counting_model` or `set_deep_counting_model_param` before calling `apply_deep_counting_model`.

When changing parameters of the Deep Counting model that influence the template creation, `prepare_deep_counting_model` must be re-run before `apply_deep_counting_model`. The list of such parameters is provided in `get_deep_counting_model_param`.

Attention

System requirements: To run this operator on GPU (see `get_deep_counting_model_param`), cuDNN and cuBLAS are required. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods". Alternatively, this operator can also be run on CPU.

Parameters

- ▷ **Templates** (input_object) (multichannel-)image(-array) $\leadsto$ *object* : byte / real
Template image(s) with regions.
- ▷ **DeepCountingHandle** (input_control) `deep_counting` $\leadsto$ *handle*
Handle of the Deep Counting model.

Result

If the handle of the model is valid, the operator `prepare_deep_counting_model` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- `DeepCountingHandle`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

read_deep_counting_model (: : FileName : DeepCountingHandle)

Read a Deep Counting model from a file.

The operator `read_deep_counting_model` reads a Deep Counting model. Such models have to be in the HALCON format. As a result, the handle `DeepCountingHandle` is returned.

The model is loaded from the file `FileName`. This file is thereby searched in the directory `$HALCONROOT/d1/` as well as in the currently used directory. The default HALCON file extension for Deep Counting models is `'.hdc'`.

Please note that the values of runtime specific parameters are not written to file, see [write_deep_counting_model](#). As a consequence when reading a model these parameters are initialized with their default value, see [get_deep_counting_model_param](#).

<i>Parameters</i>
▷ FileName (input_control)filename.read $\leadsto$ string Filename File extension: <code>.hdc</code> ▷ DeepCountingHandle (output_control)deep_counting $\leadsto$ handle Handle of the Deep Counting model.

<i>Result</i>
If the parameters are valid, the operator <code>read_deep_counting_model</code> returns the value 2 (<code>H_MSG_TRUE</code>). If necessary, an exception is raised.

<i>Execution Information</i>
• Multithreading type: reentrant (runs in parallel with non-exclusive operators). • Multithreading scope: global (may be called from any thread). • Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

set_deep_counting_model_param ( : : DeepCountingHandle,
                                GenParamName, GenParamValue : )
```

Set selected parameters of the Deep Counting model.

The operator `set_deep_counting_model_param` sets the selected parameters `GenParamName` in the Deep Counting handle `DeepCountingHandle` to the values passed in `GenParamValue`.

The possible parameters are listed and described in `get_deep_counting_model_param`.

Parameters

- ▷ **DeepCountingHandle** (input_control) `deep_counting` $\leadsto$ *handle*
Handle of the Deep Counting model.
- ▷ **GenParamName** (input_control) `attribute.name(-array)` $\leadsto$ *string*
Parameter names.
Default: 'min_score'
List of values: `GenParamName` $\in$ {'angle_start', 'angle_end', 'angle_step', 'backbone_model', 'device', 'max_overlap', 'min_score', 'scale_min', 'scale_max', 'scale_step'}
- ▷ **GenParamValue** (input_control) `attribute.value(-array)` $\leadsto$ *real / integer / string*
Parameter values.
Default: 0.5

Result

If the parameters are valid, the operator `set_deep_counting_model_param` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

18.4 Deformable

clear_deformable_model (: : ModelID :)

Free the memory of a deformable model.

The operator `clear_deformable_model` frees the memory of a deformable model that was created by `create_planar_uncalib_deformable_model` or `create_planar_calib_deformable_model`. After calling `clear_deformable_model`, the deformable model can no longer be used. The handle `ModelID` becomes invalid.

Parameters	
▷ ModelID (input_control)	deformable_model(-array) $\leadsto$ handle Handle of the model.
Result	
If the parameters are valid, the operator <code>clear_deformable_model</code> returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.	
Execution Information	
• Multithreading type: reentrant (runs in parallel with non-exclusive operators). • Multithreading scope: global (may be called from any thread). • Processed without parallelization.	
This operator modifies the state of the following input parameter:	
• <code>ModelID</code>

    Metric, Contrast, MinContrast, GenParamName,
    GenParamValue : ModelID )
```

Creates a deformable model for local, deformable matching.

The operator `create_local_deformable_model` prepares a template, which is passed in the image `Template`, as a deformable model used for local deformable matching. The ROI of the model is passed as the domain of `Template`.

The local deformable matching can be used to detect an object that is distorted by a local deformation, estimate the deformation, and rectify the image area where the object is found. For a distinction from further matching methods we refer to the "Solution Guide I" chapter '2D Matching'.

As described in `create_planar_uncalib_deformable_model`, the origin (reference point) of the model is defined as the center of gravity of the domain (region) of the model image `Template`. Further, the axis-aligned enclosing rectangle of the domain of the `Template` is used to determine the area of the search image that is rectified in calls of `find_local_deformable_model`.

For further explanation on the parameters used for the creation of a local deformable model we refer to the description of `create_planar_uncalib_deformable_model`. Note, that the parameters of the actual deformation are set with the call of `find_local_deformable_model`.

Parameters

- ▷ **Template** (input_object) (multichannel-)image $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **AngleExtent** (input_control) angle.rad-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ real / string
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep > 0 && AngleStep $\leq$ pi / 16
- ▷ **ScaleRMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in row direction.
Default: 1.0
Suggested values: ScaleRMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleRMin > 0
- ▷ **ScaleRMax** (input_control) number-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **ScaleRStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in row direction.
Default: 'auto'
Suggested values: ScaleRStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleRStep $\geq$ 0
- ▷ **ScaleCMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in column direction.
Default: 1.0
Suggested values: ScaleCMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleCMin > 0

- ▷ **ScaleCMax** (input_control) number-array $\leadsto$ *real*
This parameter is not used.
Default: []
- ▷ **ScaleCStep** (input_control) number $\leadsto$ *real* / string
Scale step length (resolution) in column direction.
Default: 'auto'
Suggested values: ScaleCStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleCStep $\geq$ 0
- ▷ **Optimization** (input_control) string(-array) $\leadsto$ *string*
Kind of optimization used for generating the model.
Default: 'none'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}
- ▷ **Metric** (input_control) string $\leadsto$ *string*
Match metric.
Default: 'use_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **Contrast** (input_control) number-array $\leadsto$ *integer* / string
Thresholds or hysteresis thresholds for the contrast of the object in the template image.
Default: 'auto'
Suggested values: Contrast $\in$ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
- ▷ **MinContrast** (input_control) number $\leadsto$ *integer* / string
Minimum contrast of the objects in the search images.
Default: 'auto'
Suggested values: MinContrast $\in$ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}
Restriction: MinContrast $<$ Contrast
- ▷ **GenParamName** (input_control) string-array $\leadsto$ *string*
The generic parameter names.
Default: []
List of values: GenParamName $\in$ {'', 'min_size', 'part_size'}
- ▷ **GenParamValue** (input_control) integer-array $\leadsto$ *integer* / *real* / string
Values of the generic parameters.
Default: []
List of values: GenParamValue $\in$ {'', 'small', 'medium', 'big'}
- ▷ **ModelID** (output_control) deformable_model $\leadsto$ *handle*
Handle of the model.

Result

If the parameters are valid, the operator `create_local_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

```

Prepare a deformable model for local deformable matching from XLD contours.

The operator `create_local_deformable_model_xld` creates a deformable model used for local deformable matching from the XLD contours passed in `Contours`. The XLD contours represent the gray-value edges of the object to be searched for. In contrast to the operator `create_local_deformable_model`, which creates a deformable model from a template image, the operator `create_local_deformable_model_xld` creates the deformable model from XLD contours.

The center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with `set_deformable_model_origin`.

For further explanation on the deformable model and its parameters we refer to the description of `create_planar_uncalib_deformable_model` and `create_local_deformable_model`. Note that `set_local_deformable_model_metric` can be used to change the metric of the model.

Attention

Note that, in contrast to the operator `create_local_deformable_model`, it is not possible to specify a minimum size of the model components. To avoid small model components in the model, short contours can be eliminated with the operator `select_contours_xld` before calling `create_local_deformable_model_xld`.

Parameters

- ▷ **Contours** (input_object) xld_cont(-array) $\leadsto$ *object*
Input contours that will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ *integer / string*
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad-array $\leadsto$ *real*
This parameter is not used.
Default: []
- ▷ **AngleExtent** (input_control) angle.rad-array $\leadsto$ *real*
This parameter is not used.
Default: []
- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ *real / string*
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep > 0 && AngleStep $\leq$ pi / 16
- ▷ **ScaleRMin** (input_control) number $\leadsto$ *real*
Minimum scale of the pattern in row direction.
Default: 1.0
Suggested values: ScaleRMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleRMin > 0
- ▷ **ScaleRMax** (input_control) number-array $\leadsto$ *real*
This parameter is not used.
Default: []

- ▷ **ScaleRStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in row direction.
Default: 'auto'
Suggested values: ScaleRStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleRStep > 0
- ▷ **ScaleCMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in column direction.
Default: 1.0
Suggested values: ScaleCMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleCMin > 0
- ▷ **ScaleCMax** (input_control) number-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **ScaleCStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in column direction.
Default: 'auto'
Suggested values: ScaleCStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleCStep > 0
- ▷ **Optimization** (input_control) string(-array) $\leadsto$ string
Kind of optimization used for generating the model.
Default: 'auto'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'ignore_local_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer
Minimum contrast of the objects in the search images.
Default: 5
Suggested values: MinContrast $\in$ {1, 2, 3, 5, 7, 10, 20, 30, 40}
- ▷ **GenParamName** (input_control) string-array $\leadsto$ string
The generic parameter names.
Default: []
List of values: GenParamName $\in$ {'', 'part_size'}
- ▷ **GenParamValue** (input_control) integer-array $\leadsto$ integer / real / string
Values of the generic parameters.
Default: []
List of values: GenParamValue $\in$ {'', 'small', 'medium', 'big'}
- ▷ **ModelID** (output_control) deformable_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_local_deformable_model_xld` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised. If the parameter `NumLevels` is chosen such that the model contains too few points, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Create a deformable model for calibrated perspective matching.

The operator `create_planar_calib_deformable_model` prepares a template, which is passed in the image [Template](#), as a deformable model used for planar calibrated matching. The ROI of the model is passed as the domain of [Template](#).

The planar calibrated matching can be used to detect the 3D pose of a planar object or planar subparts of non-planar objects that are distorted by a projective view. This is an alternative to [create_planar_uncalib_deformable_model](#), which returns the position as a 2D projective transformation (homography), but not as a metric 3D pose.

In order to determine the 3D pose, the internal camera parameters [CamParam](#) must be provided. Typically, the internal parameters are determined with the help of [calibrate_cameras](#).

Additionally to the internal camera parameters, the metric size of the image part that is passed in [Template](#) must be known. For this, a 3D reference pose that defines a 3D model plane in which the object resides must be provided with [ReferencePose](#). The 3D model plane is spanned by the x and y axis of the coordinate system defined by [ReferencePose](#).

As described in [create_planar_uncalib_deformable_model](#), the origin (reference point) of the model is defined as the center of gravity of the domain (region) of the model image [Template](#). This image point defines a ray that is cut with the plane that is provided with [ReferencePose](#) to obtain the absolute 3D model pose. This is also the absolute pose that is later returned in [find_planar_calib_deformable_model](#). Hence, the 3D pose of the model might differ from the reference pose by a 2D translation in the model plane. The final model pose can be determined by calling [get_deformable_model_params](#). The 3D model plane can be estimated by using [calibrate_cameras](#) or [vector_to_pose](#). For consistency of the coordinate systems, the [ReferencePose](#) should be aligned as if a calibration plate would be put onto the object.

For further explanation on the planar deformable model and its parameters we refer to the description of [create_planar_uncalib_deformable_model](#).

Parameters

- ▷ **Template** (input_object) (multichannel-)image $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **CamParam** (input_control) campar $\leadsto$ real / integer / string
The parameters of the internal orientation of the camera.
- ▷ **ReferencePose** (input_control) pose $\leadsto$ real / integer
The reference pose of the object in the reference image.
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **AngleExtent** (input_control) angle.rad-array $\leadsto$ real
This parameter is not used.
Default: []

- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ real / string
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep > 0 && AngleStep <= pi / 16
- ▷ **ScaleRMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in row direction.
Default: 1.0
Suggested values: ScaleRMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleRMin > 0
- ▷ **ScaleRMax** (input_control) number-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **ScaleRStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in row direction.
Default: 'auto'
Suggested values: ScaleRStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleRStep >= 0
- ▷ **ScaleCMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in column direction.
Default: 1.0
Suggested values: ScaleCMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleCMin > 0
- ▷ **ScaleCMax** (input_control) number-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **ScaleCStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in the column direction.
Default: 'auto'
Suggested values: ScaleCStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleCStep >= 0
- ▷ **Optimization** (input_control) string(-array) $\leadsto$ string
Kind of optimization used for generating the model.
Default: 'none'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **Contrast** (input_control) number-array $\leadsto$ integer / string
Thresholds or hysteresis thresholds for the contrast of the object in the template image.
Default: 'auto'
Suggested values: Contrast $\in$ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer / string
Minimum contrast of the objects in the search images.
Default: 'auto'
Suggested values: MinContrast $\in$ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}
Restriction: MinContrast < Contrast
- ▷ **GenParamName** (input_control) string-array $\leadsto$ string
The parameter names.
Default: []
List of values: GenParamName $\in$ {'', 'part_size'}
- ▷ **GenParamValue** (input_control) integer-array $\leadsto$ integer / real / string
Values of the parameters.
Default: []
List of values: GenParamValue $\in$ {'', 'small', 'medium', 'big'}

▷ **ModelID** (output_control) deformable_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_planar_calib_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Prepare a deformable model for planar calibrated matching from XLD contours.

The operator `create_planar_calib_deformable_model_xld` creates a deformable model used for planar calibrated matching from the XLD contours passed in `Contours`. The XLD contours represent the gray-value edges of the object to be searched for. In contrast to the operator `create_planar_calib_deformable_model`, which creates a deformable model from a template image, the operator `create_planar_calib_deformable_model_xld` creates the deformable model from XLD contours. Note that the operator expects `Contours` to be in a metric world coordinate system. This is in contrast to `create_planar_uncalib_deformable_model_xld`, where the `Contours` are provided in image coordinates.

Further, the origin (reference point) of the model is taken directly from the provided `Contours`. This is in contrast to `create_planar_uncalib_deformable_model_xld`, where the center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used. A different origin in the world coordinate system can be set with `set_deformable_model_origin`.

For further explanation on the planar deformable model and its parameters we refer to the description of `create_planar_uncalib_deformable_model` and `create_planar_calib_deformable_model`.

Attention

Note that, in contrast to the operator `create_planar_calib_deformable_model`, it is not possible to specify a minimum size of the model components. To avoid small model components in the model, short contours can be eliminated before calling `create_planar_calib_deformable_model_xld` with the operator `select_contours_xld`.

Parameters

-
- ▷ **Contours** (input_object) xld_cont(-array) $\leadsto$ *object*
Input contours that will be used to create the model.
 - ▷ **CamParam** (input_control) campar $\leadsto$ *real / integer / string*
The parameters of the internal orientation of the camera.
 - ▷ **ReferencePose** (input_control) pose $\leadsto$ *real / integer*
The reference pose of the object.
 - ▷ **NumLevels** (input_control) integer $\leadsto$ *integer / string*
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
 - ▷ **AngleStart** (input_control) angle.rad-array $\leadsto$ *real*
This parameter is not used.
Default: []
 - ▷ **AngleExtent** (input_control) angle.rad-array $\leadsto$ *real*
This parameter is not used.
Default: []
 - ▷ **AngleStep** (input_control) angle.rad $\leadsto$ *real / string*
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep > 0 && AngleStep $\leq$ pi / 16
 - ▷ **ScaleRMin** (input_control) number $\leadsto$ *real*
Minimum scale of the pattern in row direction.
Default: 1.0
Suggested values: ScaleRMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleRMin > 0
 - ▷ **ScaleRMax** (input_control) number-array $\leadsto$ *real*
This parameter is not used.
Default: []
 - ▷ **ScaleRStep** (input_control) number $\leadsto$ *real / string*
Scale step length (resolution) in row direction.
Default: 'auto'
Suggested values: ScaleRStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleRStep > 0
 - ▷ **ScaleCMin** (input_control) number $\leadsto$ *real*
Minimum scale of the pattern in column direction.
Default: 1.0
Suggested values: ScaleCMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleCMin > 0
 - ▷ **ScaleCMax** (input_control) number-array $\leadsto$ *real*
This parameter is not used.

 - ▷ **ScaleCStep** (input_control) number $\leadsto$ *real / string*
Scale step length (resolution) in the column direction.
Default: 'auto'
Suggested values: ScaleCStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleCStep > 0
 - ▷ **Optimization** (input_control) string(-array) $\leadsto$ *string*
Kind of optimization used for generating the model.
Default: 'auto'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}
 - ▷ **Metric** (input_control) string $\leadsto$ *string*
Match metric.
Default: 'ignore_local_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_part_polarity',

- 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer
Minimum contrast of the objects in the search images.
Default: 5
Suggested values: MinContrast $\in$ {1, 2, 3, 5, 7, 10, 20, 30, 40}
 - ▷ **GenParamName** (input_control) string-array $\leadsto$ string
The generic parameter names.
Default: []
List of values: GenParamName $\in$ {[], 'part_size'}
 - ▷ **GenParamValue** (input_control) integer-array $\leadsto$ integer / real / string
Values of the generic parameter.
Default: []
List of values: GenParamValue $\in$ {[], 'small', 'medium', 'big'}
 - ▷ **ModelID** (output_control) deformable_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_planar_calib_deformable_model_xld` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised. If the parameter `NumLevels` is chosen such that the model contains too few points, the error 8510 is raised.

Creates a deformable model for uncalibrated, perspective matching.

The operator `create_planar_uncalib_deformable_model` prepares a template, which is passed in the image `Template`, as a deformable model used for uncalibrated perspective matching. The ROI of the model is passed as the domain of `Template`.

The planar uncalibrated matching can be used to detect planar objects or planar subparts of non-planar objects that are distorted by a projective view.

This is an alternative to `create_generic_shape_model`, where typically the search image must be rectified by `calibrate_cameras` and `gen_image_to_world_plane_map` beforehand.

In contrast to `create_shape_model_3d` there is no need to pre-generate different views of an object, resulting into a smaller memory consumption. Hence, in case of a planar perspectively distorted object, `create_planar_uncalib_deformable_model` should be preferred.

The model is generated using multiple image pyramid levels and is stored in memory. The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_planar_uncalib_deformable_model`.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_planar_uncalib_deformable_model` returns with an error message. If `NumLevels` is set to `'auto'`, `create_planar_uncalib_deformable_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_deformable_model_params`. In rare cases, it might happen that `create_planar_uncalib_deformable_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_planar_uncalib_deformable_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_planar_uncalib_deformable_model` increases. In these cases, the number of pyramid levels should be selected using the output of `inspect_shape_model`.

Angle and Scale parameters: Note that the parameters `AngleStart`, `AngleExtent`, `ScaleRMax`, and `ScaleCMax` are not used by this operator. Instead, they have to be specified within the operator `find_planar_uncalib_deformable_model`. `ScaleRMin` and `ScaleCMin` can be relevant if you expect matches that are smaller than in the original image `Template`. Then, if `NumLevels` is set to `'auto'`, the number of used pyramid levels may decrease.

Generally, the parameters `AngleStep`, `ScaleRStep` and `ScaleCStep` can be determined automatically. The automatically computed angle and scale step lengths can be queried using `get_deformable_model_params`. For more information about how these parameters work, please refer to the operator `find_planar_uncalib_deformable_model`.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from `'none'`. If `Optimization = 'none'`, all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_planar_uncalib_deformable_model` to set the parameter `Score` and `Greediness` to a smaller value as, e.g., `0.7` or `0.8`. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined. If `Optimization` is set to `'auto'`, `create_planar_uncalib_deformable_model` automatically determines the reduction of the number of model points.

Contrast: The parameter `Contrast` determines the contrast the model points (edges) must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. `Contrast` should be chosen such that only the significant features of the template are used for the model.

The following values can be set for `Contrast`:

- A single contrast value. You can set:
 - an integer value: the manually determined value is used.
 - `'auto_contrast'`: the contrast value is computed automatically.
- Hysteresis thresholds. In this case, the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. For more information about the hysteresis threshold method, see `hysteresis_threshold`. You can set:
 - A tuple of two values: The first value determines the lower threshold, the second value determines the upper threshold.
 - `'auto'` (default value) or `'auto_contrast_hyst'`: The hysteresis thresholds are computed automatically.

In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with `determine_deformable_model_params` and subsequently verified using `inspect_shape_model` before calling `create_planar_uncalib_deformable_model`. Note that `MinContrast` influences the automatic contrast estimation, and hence also the estimation of the minimum size.

MinContrast: With `MinContrast`, it can be determined which minimal contrast the model must have in the recognition performed by `find_planar_uncalib_deformable_model`. In other words, this parameter separates the model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, `MinContrast` should be set to 10. Obviously, `MinContrast` must be smaller than `Contrast`. If the model should be recognized in very low contrast images, `MinContrast` must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, `MinContrast` should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by `find_planar_uncalib_deformable_model`. If `MinContrast` is set to 'auto', the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using `get_deformable_model_params`. The `MinContrast` of a deformable model can later be changed with the help of `set_deformable_model_param`.

Metric: The parameter `Metric` determines the conditions under which the model is recognized in the image. If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_planar_uncalib_deformable_model` will increase slightly in this case. If `Metric = 'ignore_part_polarity'`, the contrast polarity is allowed to change only between different parts of the model, whereas the polarity of model points that are within the same model part must not change. Please note that the term 'ignore_part_polarity' is capable of being misunderstood. It means that polarity changes between neighboring model parts do not influence the score, and hence are ignored. If `Metric = 'ignore_local_polarity'`, the model is found even if the contrast changes for each individual model point. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. In this case the runtime of `find_planar_uncalib_deformable_model` increases significantly. The above four metrics can only be applied to single-channel images. If a multi-channel image is used as the model image or as the search image only the first channel will be used (and no error message will be returned). If `Metric = 'ignore_color_polarity'`, the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_planar_uncalib_deformable_model` can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'. It should be noted that for `Metric = 'ignore_color_polarity'` the number of channels in the model creation with `create_planar_uncalib_deformable_model` and in the search with `find_planar_uncalib_deformable_model` can be different. This can, for example, be used to create a model from a synthetically generated single-channel image. Furthermore, it should be noted that the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

GenParamName, GenParamValue: With the help of the generic parameters `GenParamName` and `GenParamValue`, the user can set parameters for the deformable model generation.

The following parameters can be set for `GenParamName`.

'part_size': Adapts the average size of the sub-parts that the deformable model should consist of. For objects that consist of many small contours, 'small' should be selected. For objects that consist of only big contours, 'big' should be set.

List of values: 'small', 'medium', 'big'

Default: 'big'.

'min_size': Determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size specified in the corresponding `GenParamValue` are suppressed. This threshold for the minimum size is divided by two for each successive pyramid level. 'min_size' can be set to an arbitrary integer value greater or equal 0. It can also be set to 'auto' which means that the minimum size will be determined automatically.

Default: 'auto'

The center of gravity of the domain (region) of the model image `Template` is used as the origin (reference point) of the model. A different origin for the model can be set with `set_deformable_model_origin`.

Parameters

- ▷ **Template** (input_object) (multichannel-)image $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **AngleExtent** (input_control) angle.rad-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ real / string
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep > 0 && AngleStep $\leq$ pi / 16
- ▷ **ScaleRMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in row direction.
Default: 1.0
Suggested values: ScaleRMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleRMin > 0
- ▷ **ScaleRMax** (input_control) number-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **ScaleRStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in row direction.
Default: 'auto'
Suggested values: ScaleRStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleRStep $\geq$ 0
- ▷ **ScaleCMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in column direction.
Default: 1.0
Suggested values: ScaleCMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleCMin > 0
- ▷ **ScaleCMax** (input_control) number-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **ScaleCStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in column direction.
Default: 'auto'
Suggested values: ScaleCStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleCStep $\geq$ 0

- ▷ **Optimization** (input_control) string(-array) $\leadsto$ string
Kind of optimization used for generating the model.
Default: 'none'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **Contrast** (input_control) number-array $\leadsto$ integer / string
Thresholds or hysteresis thresholds for the contrast of the object in the template image.
Default: 'auto'
Suggested values: Contrast $\in$ {'auto', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer / string
Minimum contrast of the objects in the search images.
Default: 'auto'
Suggested values: MinContrast $\in$ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}
Restriction: MinContrast < Contrast
- ▷ **GenParamName** (input_control) string-array $\leadsto$ string
The generic parameter names.
Default: []
List of values: GenParamName $\in$ {'', 'min_size', 'part_size'}
- ▷ **GenParamValue** (input_control) integer-array $\leadsto$ integer / real / string
Values of the generic parameter.
Default: []
List of values: GenParamValue $\in$ {'', 'small', 'medium', 'big'}
- ▷ **ModelID** (output_control) deformable_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_planar_uncalib_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

```
create_planar_uncalib_deformable_model_xld (
    Contours : : NumLevels, AngleStart, AngleExtent, AngleStep,
    ScaleRMin, ScaleRMax, ScaleRStep, ScaleCMin, ScaleCMax,
    ScaleCStep, Optimization, Metric, MinContrast, GenParamName,
    GenParamValue : ModelID )
```

Prepare a deformable model for planar uncalibrated matching from XLD contours.

The operator `create_planar_uncalib_deformable_model_xld` creates a deformable model used for planar uncalibrated matching from the XLD contours passed in `Contours`. The XLD contours represent the gray-value edges of the object to be searched for. In contrast to the operator `create_planar_uncalib_deformable_model`, which creates a deformable model from a template image, the operator `create_planar_uncalib_deformable_model_xld` creates the deformable model from XLD contours.

The model is generated for multiple image pyramid levels and is stored in memory. The center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with `set_deformable_model_origin`. The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_planar_uncalib_deformable_model`.

Some Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure leads to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_planar_uncalib_deformable_model_xld` returns with an error message. If `NumLevels` is set to 'auto', `create_planar_uncalib_deformable_model_xld` determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using `get_deformable_model_params`. In rare cases, it might happen that `create_planar_uncalib_deformable_model_xld` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the search image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_planar_uncalib_deformable_model` to find the object. If the number of pyramid levels is chosen too small, the time required to find the object with `find_planar_uncalib_deformable_model` may increase. In both cases, the number of pyramid levels should be selected manually.

Angle and Scale parameters: Note that the parameters `AngleStart`, `AngleExtent`, `ScaleRMax`, and `ScaleCMax` are not used by this operator. Instead, they have to be specified within the operator `find_planar_uncalib_deformable_model`. `ScaleRMin` and `ScaleCMin` can be relevant if you expect matches that are smaller than the given XLD `Contours`. Then, if `NumLevels` is set to 'auto', the number of used pyramid levels may decrease.

Generally, the parameters `AngleStep`, `ScaleRStep` and `ScaleCStep` can be determined automatically. The automatically computed angle and scale step lengths can be queried using `get_deformable_model_params`. For more information about how these parameters work, please refer to the operator `find_planar_uncalib_deformable_model`.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from 'none'. If `Optimization = 'none'` is set, all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_planar_uncalib_deformable_model` to set the parameter `Score` and `Greediness` to a smaller value as, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search, because in this case usually significantly more potential instances of the model must be examined. If `Optimization` is set to 'auto', `create_planar_uncalib_deformable_model_xld` automatically determines the reduction of the number of model points.

MinContrast: With `MinContrast`, it can be determined which contrast the object contours must at least have in the recognition performed by `find_planar_uncalib_deformable_model`. In other words,

this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray-value changes caused by the noise in the image. If, e.g., the gray values fluctuate within a range of 10 gray levels, `MinContrast` should be set to 10. If multi-channel images are used for the model and the search images, and if the parameter `Metric` is set to `'ignore_color_polarity'` (see below) the noise in one channel must be multiplied by the square root of the number of channels to determine `MinContrast`. If, e.g., the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image, `MinContrast` should be set to 17. If the model should be recognized in very low contrast images, `MinContrast` must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, `MinContrast` should be slightly larger than the range of gray value fluctuations created by noise to ensure that the position and rotation of the model are extracted robustly and accurately by `find_planar_uncalib_deformable_model`.

Metric: The parameter `Metric` determines the conditions under which the model is recognized in the image. If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_planar_uncalib_deformable_model` will increase slightly in this case. If `Metric = 'ignore_part_polarity'` or `Metric = 'ignore_local_polarity'`, the model is found even if the contrast changes locally. These modes can, e.g., be useful if the object consists of a part with a medium gray value, within which either darker or brighter sub-objects lie. The above mentioned four metrics can only be applied to single-channel images. If a multi-channel image is used as the search image, only the first channel will be used (and no error message will be returned). If `Metric = 'ignore_color_polarity'`, the model is found even if the color contrast changes locally. This is, e.g., the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_planar_uncalib_deformable_model` can also increase significantly. The metric `'ignore_color_polarity'` can be used for images with an arbitrary number of channels. If it is used for single-channel images, it has the same effect as `'ignore_local_polarity'`. It should be noted that for `Metric = 'ignore_color_polarity'` the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, e.g., also contain images of the same object that were obtained by illuminating the object from different directions. Note that the first two metrics (`'use_polarity'` and `'ignore_global_polarity'`) can only be selected if all `Contours` provide the attribute `'edge_direction'`, which defines the polarity of the contained contours. For more information about contour attributes like `'edge_direction'` see `get_contour_attrib_xld`. Otherwise, these two metrics can be selected with the operator `set_planar_uncalib_deformable_model_metric`, which determines the polarity of the model contours from a representative image.

Attention

Note that, in contrast to the operator `create_planar_uncalib_deformable_model`, it is not possible to specify a minimum size of the model components. To avoid small model components in the model, short contours can be eliminated before calling `create_planar_uncalib_deformable_model_xld` with the operator `select_contours_xld`.

Parameters

- ▷ **Contours** (input_object) `xld_cont(-array)` $\leadsto$ *object*
Input contours that will be used to create the model.
- ▷ **NumLevels** (input_control) `integer` $\leadsto$ *integer / string*
Maximum number of pyramid levels.
Default: `'auto'`
Suggested values: `NumLevels` $\in$ `{'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}`
- ▷ **AngleStart** (input_control) `angle.rad-array` $\leadsto$ *real*
This parameter is not used.
Default: `[]`
- ▷ **AngleExtent** (input_control) `angle.rad-array` $\leadsto$ *real*
This parameter is not used.
Default: `[]`

- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ real / string
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep > 0 && AngleStep <= pi / 16
- ▷ **ScaleRMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in row direction.
Default: 1.0
Suggested values: ScaleRMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleRMin > 0
- ▷ **ScaleRMax** (input_control) number-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **ScaleRStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in row direction.
Default: 'auto'
Suggested values: ScaleRStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleRStep > 0
- ▷ **ScaleCMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in column direction.
Default: 1.0
Suggested values: ScaleCMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleCMin > 0
- ▷ **ScaleCMax** (input_control) number-array $\leadsto$ real
This parameter is not used.
Default: []
- ▷ **ScaleCStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in the column direction.
Default: 'auto'
Suggested values: ScaleCStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleCStep > 0
- ▷ **Optimization** (input_control) string(-array) $\leadsto$ string
Kind of optimization used for generating the model.
Default: 'auto'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'ignore_local_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_part_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer
Minimum contrast of the objects in the search images.
Default: 5
Suggested values: MinContrast $\in$ {1, 2, 3, 5, 7, 10, 20, 30, 40}
- ▷ **GenParamName** (input_control) string-array $\leadsto$ string
The generic parameter names.
Default: []
List of values: GenParamName $\in$ {'', 'part_size'}
- ▷ **GenParamValue** (input_control) integer-array $\leadsto$ integer / real / string
Values of the generic parameters.
Default: []
List of values: GenParamValue $\in$ {'', 'small', 'medium', 'big'}
- ▷ **ModelID** (output_control) deformable_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_planar_uncalib_deformable_model_xld` returns the

value 2 (H_MSG_TRUE). If necessary, an exception is raised. If the parameter `NumLevels` is chosen such that the model contains too few points, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

```
deserialize_deformable_model (
    : : SerializedItemHandle : ModelID )
```

Deserialize a deformable model.

`deserialize_deformable_model` deserializes a deformable model, that was serialized by `serialize_deformable_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized deformable model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created deformable model with the handle `ModelID`.

Parameters

- ▷ **SerializedItemHandle** (input_control) `serialized_item` $\leadsto$ *handle*
Handle of the serialized item.
- ▷ **ModelID** (output_control) `deformable_model` $\leadsto$ *handle*
Handle of the model.

Result

If the parameters are valid, the operator `deserialize_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
determine_deformable_model_params ( Template : : NumLevels,
    AngleStart, AngleExtent, ScaleMin, ScaleMax, Optimization,
    Metric, Contrast, MinContrast, GenParamName, GenParamValue,
    Parameters : ParameterName, ParameterValue )
```

Determine the parameters of a deformable model.

`determine_deformable_model_params` determines certain parameters of a deformable model automatically from the model image `Template`. The parameters to be determined can be specified with `Parameters`. `determine_deformable_model_params` can be used to determine the same parameters that are determined automatically when the respective parameter in `create_planar_uncalib_deformable_model` is set to 'auto': the number of pyramid levels (`Parameters = 'num_levels'`), the angle step length (`Parameters = 'angle_step'`), the scale step length (`Parameters = 'scale_step'` for isotropic scaling and 'scale_r_step' and/or 'scale_c_step' for anisotropic scaling), the kind of optimization (`Parameters = 'optimization'`), the threshold (`Parameters = 'contrast'`) or the hysteresis thresholds (`Parameters = 'contrast_hyst'`) for the contrast, the minimum size of the object parts (`Parameters = 'min_size'`), and the minimum contrast (`Parameters = 'min_contrast'`). By passing a tuple of the above values in `Parameters`, an arbitrary combination of these parameters can be determined. If all of the above parameters should be determined, the value 'all' can be passed. In this case both hysteresis thresholds are determined, i.e., the operator behaves like passing 'contrast_hyst' instead of 'contrast'.

`determine_deformable_model_params` is mainly useful to determine the above parameters before creating the model, e.g., in an interactive system, which makes suggestions for these parameters to the user, but enables the user to modify the suggested values.

The automatically determined parameters are returned as a name-value pair in `ParameterName` and `ParameterValue`. The parameter names in `ParameterName` are identical to the names in `Parameters`, where, of course, the value 'all' is replaced by the actual parameter names. An exception is the parameter 'contrast_hyst', for which the two values 'contrast_low' and 'contrast_high' are returned.

The remaining parameters (`NumLevels`, `AngleStart`, `AngleExtent`, `ScaleMin`, `ScaleMax`, `Optimization`, `Metric`, `Contrast`, and `MinContrast`) have the same meaning as in `create_planar_uncalib_deformable_model` and `find_planar_uncalib_deformable_model`. The description of these parameters can be looked up with these operators. These parameters are used by `determine_deformable_model_params` to calculate the parameters to be determined in the same manner as in `create_planar_uncalib_deformable_model`. It should be noted that if the parameters of a deformable model with isotropic scaling should be determined, i.e., if `Parameters` contains 'scale_step' either explicitly or implicitly via 'all', the parameters `ScaleMin` and `ScaleMax` must contain one value each. If the parameters of a deformable model with anisotropic scaling should be determined, i.e., if `Parameters` contains 'scale_r_step' or 'scale_c_step' either explicitly or implicitly, the parameters `ScaleMin` and `ScaleMax` must contain two values each. In this case, the first value of the respective parameter refers to the scaling in row direction, while the second value refers to scaling in the column direction.

Note that in `determine_deformable_model_params` some parameters appear that can also be determined automatically (`NumLevels`, `Optimization`, `Contrast`, `MinContrast`). If these parameters should not be determined automatically, i.e., their name is not passed in `ParameterName`, the corresponding parameters must contain valid values and must not be set to 'auto'. In contrast, if these parameters are to be determined automatically, their values are treated in the following way: If the optimization or the (hysteresis) contrast is to be determined automatically, i.e., `ParameterName` contains the value 'optimization' or 'contrast' ('contrast_hyst'), the values passed in `Optimization` and `Contrast` are ignored. In contrast, if the maximum number of pyramid levels or the minimum contrast is to be determined automatically, i.e., `ParameterName` contains the value 'num_levels' or 'min_contrast', you can let HALCON determine suitable values and at the same time specify an upper or lower boundary, respectively:

If the maximum number of pyramid levels should be specified in advance, `NumLevels` can be set to the particular value. If in this case `Parameters` contains the value 'num_levels', the computed number of pyramid levels is at most `NumLevels`. If `NumLevels` is set to 'auto' (or 0 for backwards compatibility), the number of pyramid levels is determined without restrictions as large as possible.

If the minimum contrast should be specified in advance, `MinContrast` can be set to the particular value. If in this case `Parameters` contains the value 'min_contrast', the computed minimum contrast is at least `MinContrast`. If `MinContrast` is set to 'auto', the minimum contrast is determined without restrictions.

If the user wishes to create a calibrated, deformable model with `create_planar_calib_deformable_model`, the internal camera parameters are needed for the correct estimation of the parameters in `ParameterValue`.

The camera parameters can be provided by setting `GenParamName` to `'cam_param'` and providing the tuple containing the camera parameters in `GenParamValue`.

Parameters

- ▷ **Template** (input_object) (multichannel-)image $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the model.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in$ {6.28, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtent $\geq$ 0
- ▷ **ScaleMin** (input_control) number(-array) $\leadsto$ real
Minimum scale of the model.
Default: 0.9
Suggested values: ScaleMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleMin $>$ 0
- ▷ **ScaleMax** (input_control) number(-array) $\leadsto$ real
Maximum scale of the model.
Default: 1.1
Suggested values: ScaleMax $\in$ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
Restriction: ScaleMax $\geq$ ScaleMin
- ▷ **Optimization** (input_control) string $\leadsto$ string
Kind of optimization.
Default: 'auto'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **Contrast** (input_control) number(-array) $\leadsto$ integer / string
Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
Default: 'auto'
Suggested values: Contrast $\in$ {'auto', 'auto_contrast', 'auto_contrast_hyst', 'auto_min_size', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer / string
Minimum contrast of the objects in the search images.
Default: 'auto'
Suggested values: MinContrast $\in$ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}
Restriction: MinContrast $<$ Contrast
- ▷ **GenParamName** (input_control) string-array $\leadsto$ string
The general parameter names.
Default: []
List of values: GenParamName $\in$ {'cam_param'}
- ▷ **GenParamValue** (input_control) number-array $\leadsto$ real / integer / string
Values of the general parameter.
Default: []
List of values: GenParamValue $\in$ {[]}

- ▷ **Parameters** (input_control) string(-array) $\leadsto$ string
Parameters to be determined automatically.
Default: 'all'
List of values: Parameters $\in$ {'all', 'num_levels', 'angle_step', 'scale_step', 'scale_r_step', 'scale_c_step', 'optimization', 'contrast', 'contrast_hyst', 'min_size', 'min_contrast'}
- ▷ **ParameterName** (output_control) string-array $\leadsto$ string
Name of the automatically determined parameter.
- ▷ **ParameterValue** (output_control) number-array $\leadsto$ real / integer
Value of the automatically determined parameter.

Result

If the parameters are valid, the operator `determine_deformable_model_params` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised. If the parameters `NumLevels` and `Contrast` are chosen such that the model contains too few points, or the input image does not contain a sufficient number of significant features, the error message 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
find_local_deformable_model ( Image : ImageRectified, VectorField,
    DeformedContours : ModelID, AngleStart, AngleExtent, ScaleRMin,
    ScaleRMax, ScaleCMin, ScaleCMax, MinScore, NumMatches,
    MaxOverlap, NumLevels, Greediness, ResultType, GenParamName,
    GenParamValue : Score, Row, Column )
```

Find the best matches of a local deformable model in an image.

The operator `find_local_deformable_model` finds the best `NumMatches` instances of the locally deformable model `ModelID` in the input `Image`. The model must have been created previously by calling `create_local_deformable_model` or `read_deformable_model`.

The model is searched within those points of the domain of the image in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore`. Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with `set_system('border_shape_models', 'true')`, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.

The operator `find_local_deformable_model` returns the `Row` and `Column` coordinates of the found instances. Additionally, a rectified part of the image, the respective vector field, and the contours of the found deformed model instance can be returned in `ImageRectified`, `VectorField`, and `DeformedContours`. By default, these iconic objects are not returned. In case that they are needed the parameter `ResultType` should be set to 'image_rectified', 'vector_field' and 'deformed_contours'. The size of `ImageRectified` and

VectorField is the smallest axis-aligned rectangle of the domain of the image that was used to create the local deformable model with `create_local_deformable_model`. The size of the rectified image and the vector field can be expanded in all directions by setting **GenParamName** to 'expand_border' and the respective **GenParamValue** to the number of pixels. Optionally, a specific direction can be selected with 'expand_border_top', 'expand_border_bottom', 'expand_border_left', and 'expand_border_right'. Please note that the returned **VectorField** is in absolute coordinates and can be used for `convert_map_type`.

The smoothness of the estimated deformation can be selected with **GenParamName** set to 'deformation_smoothness'. The value for 'deformation_smoothness' can be imagined as the size of a smoothing filter to the estimated deformation field. A too small value expects a strong deformation a too big value expects a rigid object. The minimal value for 'deformation_smoothness' is 3, a typical value is 11, and the value can be increased further for only small global deformations.

Finally, the score of each found instance is returned in **Score**. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image.

For further explanation on the parameters used for the search of a local deformable model we refer to the description of `find_planar_uncalib_deformable_model`.

Parameters

- ▷ **Image** (input_object)(multichannel-)image $\leadsto$ object : byte / uint2
Input image in which the model should be found.
- ▷ **ImageRectified** (output_object) (multichannel-)image(-array) $\leadsto$ object : byte / uint2
Rectified image of the found model.
- ▷ **VectorField** (output_object) singlechannelimage(-array) $\leadsto$ object : vector_field
Vector field of the rectification transformation.
- ▷ **DeformedContours** (output_object) xld_cont-array $\leadsto$ object
Contours of the found instances of the model.
- ▷ **ModelID** (input_control) deformable_model $\leadsto$ handle
Handle of the model.
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the model.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
- ▷ **ScaleRMin** (input_control) number $\leadsto$ real
Minimum scale of the model in row direction.
Default: 1.0
Suggested values: ScaleRMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleRMin > 0
- ▷ **ScaleRMax** (input_control) number $\leadsto$ real
Maximum scale of the model in row direction.
Default: 1.0
Suggested values: ScaleRMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleRMax $\geq$ ScaleRMin
- ▷ **ScaleCMin** (input_control) number $\leadsto$ real
Minimum scale of the model in column direction.
Default: 1.0
Suggested values: ScaleCMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleCMin > 0
- ▷ **ScaleCMax** (input_control) number $\leadsto$ real
Maximum scale of the model in column direction.
Default: 1.0
Suggested values: ScaleCMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleCMax $\geq$ ScaleCMin

- ▷ **MinScore** (input_control) real $\rightsquigarrow$ real
Minimum score of the instances of the model to be found.
Default: 0.5
Suggested values: MinScore $\in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control) integer $\rightsquigarrow$ integer
Number of instances of the model to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in \{0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **MaxOverlap** (input_control) real $\rightsquigarrow$ real
Maximum overlap of the instances of the model to be found.
Default: 1.0
Suggested values: MaxOverlap $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumLevels** (input_control) integer $\rightsquigarrow$ integer
Number of pyramid levels used in the matching.
Default: 0
List of values: NumLevels $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$
- ▷ **Greediness** (input_control) real $\rightsquigarrow$ real
“Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: Greediness $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{Greediness} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **ResultType** (input_control) string-array $\rightsquigarrow$ string
Switch for requested iconic result.
Default: []
List of values: ResultType $\in \{[], \text{'image_rectified'}, \text{'vector_field'}, \text{'deformed_contours'}\}$
- ▷ **GenParamName** (input_control) string-array $\rightsquigarrow$ string
The general parameter names.
Default: []
List of values: GenParamName $\in \{[], \text{'subpixel'}, \text{'angle_step'}, \text{'scale_r_step'}, \text{'scale_c_step'}, \text{'deformation_smoothness'}, \text{'expand_border'}, \text{'expand_border_top'}, \text{'expand_border_bottom'}, \text{'expand_border_left'}, \text{'expand_border_right'}\}$
- ▷ **GenParamValue** (input_control) integer-array $\rightsquigarrow$ integer / real / string
Values of the general parameters.
Default: []
List of values: GenParamValue $\in \{[], \text{'none'}, \text{'least_squares'}, \text{'least_squares_high'}, \text{'least_squares_very_high'}\}$
- ▷ **Score** (output_control) real-array $\rightsquigarrow$ real
Scores of the found instances of the model.
- ▷ **Row** (output_control) real-array $\rightsquigarrow$ real
Row coordinates of the found instances of the model.
- ▷ **Column** (output_control) real-array $\rightsquigarrow$ real
Column coordinates of the found instances of the model.

Result

If the parameters are valid, the operator `find_local_deformable_model` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

`create_local_deformable_model`, `create_local_deformable_model_xld`,
`read_deformable_model`

Module

Matching

```
find_planar_calib_deformable_model ( Image : : ModelID,
    AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin,
    ScaleCMax, MinScore, NumMatches, MaxOverlap, NumLevels,
    Greediness, GenParamName, GenParamValue : Pose, CovPose, Score )
```

Find the best matches of a calibrated deformable model in an image and return their 3D pose.

The operator `find_planar_calib_deformable_model` finds the best `NumMatches` instances of the calibrated deformable model `ModelID` in the input image `Image`. The model must have been created previously by calling `create_planar_calib_deformable_model` or `read_deformable_model`. The operator `find_planar_calib_deformable_model` returns the 3D `Pose` of the found instances in the camera coordinate system.

Additionally, the accuracy of the six pose parameters are returned in `CovPose`. By default, `CovPose` contains the 6 standard deviations of the pose parameters for each match. If the generic parameter '`cov_pose_mode`' was set to '`covariances`', `CovPose` contains the 36 values of the complete 6×6 covariance matrix of the 6 pose parameters. Note that this reflects only an inner accuracy from which the real accuracy of the pose may differ. Finally, the score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image.

For further explanation on the planar deformable model and its parameters we refer to the description of `find_planar_uncalib_deformable_model`.

Parameters

- ▷ **Image** (input_object)(multichannel-)image $\leadsto$ object : byte / uint2
Input image in which the model should be found.
- ▷ **ModelID** (input_control) deformable_model $\leadsto$ handle
Handle of the model.
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the model.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.78, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.78
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.78, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
- ▷ **ScaleRMin** (input_control) number $\leadsto$ real
Minimum scale of the model in row direction.
Default: 1.0
Suggested values: ScaleRMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleRMin > 0
- ▷ **ScaleRMax** (input_control) number $\leadsto$ real
Maximum scale of the model in row direction.
Default: 1.0
Suggested values: ScaleRMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleRMax $\geq$ ScaleRMin

- ▷ **ScaleCMin** (input_control) number $\leadsto$ real
Minimum scale of the model in column direction.
Default: 1.0
Suggested values: ScaleCMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleCMin > 0
- ▷ **ScaleCMax** (input_control) number $\leadsto$ real
Maximum scale of the model in column direction.
Default: 1.0
Suggested values: ScaleCMax $\in$ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
Restriction: ScaleCMax $\geq$ ScaleCMin
- ▷ **MinScore** (input_control) real $\leadsto$ real
Minimum score of the instances of the model to be found.
Default: 0.5
Suggested values: MinScore $\in$ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control) integer $\leadsto$ integer
Number of instances of the model to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in$ {0, 1, 2, 3, 4, 5, 10, 20}
- ▷ **MaxOverlap** (input_control) real $\leadsto$ real
Maximum overlap of the instances of the model to be found.
Default: 1.0
Suggested values: MaxOverlap $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumLevels** (input_control) integer(-array) $\leadsto$ integer
Number of pyramid levels used in the matching (and lowest pyramid level to use if |NumLevels| = 2).
Default: 0
List of values: NumLevels $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **Greediness** (input_control) real $\leadsto$ real
“Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: Greediness $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{Greediness} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **GenParamName** (input_control) string-array $\leadsto$ string
The general parameter names.
Default: []
List of values: GenParamName $\in$ {[], 'subpixel', 'angle_change_restriction', 'aniso_scale_change_restriction', 'angle_step', 'scale_r_step', 'scale_c_step', 'cov_pose_mode'}
- ▷ **GenParamValue** (input_control) integer-array $\leadsto$ integer / real / string
Values of the general parameters.
Default: []
List of values: GenParamValue $\in$ {[], 'least_squares', 'least_squares_high', 'least_squares_very_high', 'standard_deviations', 'covariances'}
- ▷ **Pose** (output_control) pose(-array) $\leadsto$ real / integer
Pose of the object.
- ▷ **CovPose** (output_control) real-array $\leadsto$ real
6 standard deviations or 36 covariances of the pose parameters.
- ▷ **Score** (output_control) real-array $\leadsto$ real
Score of the found instances of the model.

Result

If the parameters are valid, the operator `find_planar_calib_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

`create_planar_calib_deformable_model`, `read_deformable_model`

Module

Matching

```
find_planar_uncalib_deformable_model ( Image : : ModelID,
    AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin,
    ScaleCMax, MinScore, NumMatches, MaxOverlap, NumLevels,
    Greediness, GenParamName, GenParamValue : HomMat2D, Score )
```

Find the best matches of a planar projective invariant deformable model in an image.

The operator `find_planar_uncalib_deformable_model` finds the best `NumMatches` instances of the perspectively distorted deformable model `ModelID` in the input image `Image`. The model must have been created previously by calling `create_planar_uncalib_deformable_model` or `read_deformable_model`.

`HomMat2D` determines the projective transformation (homography), which describes the position of the found matches. In case several objects are found, the different homographies are concatenated. Then, a single homography can be extracted using `tuple_select_range` (`HomMat2D`, `Index*9`, `(Index+1)`). The different results are sorted according to their `Score` in descending order.

The row and column coordinates of the origin of the deformable model within the search image can be determined calling `projective_trans_pixel` (`HomMat2D`, `0`, `0`, `Row`, `Column`). Usually the origin of the model is the center of gravity of the image region used to create the deformable model calling `create_planar_uncalib_deformable_model`. The origin can be modified using `set_deformable_model_origin`.

The model contours of found instances can be visualized using `projective_trans_contour_xld` with the `HomMat2D` and the original model contour, which has been extracted previously using `get_deformable_model_contours`.

The `Score` is a number between 0 and 1 and may indicate how much of the model is visible within the image.

Example: Half of the model is occluded in the search image. As a result, the `Score` of this match can not exceed 0.5.

Input parameters in detail

Image and its domain: The domain of the image `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the deformable model with `create_planar_uncalib_deformable_model`. A different origin set with `set_deformable_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with `set_system('border_shape_models', 'true')`, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.

Angle and Scale parameters: The parameters `AngleStart`, `AngleExtent`, `ScaleRMin`, `ScaleRMax`, `ScaleCMin` and `ScaleCMax` are used to specify a basic range of up to an anisotropic transformation that is exhaustively searched on the top level of the image pyramid. The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations in which the model is exhaustively searched. `ScaleRMin`, `ScaleRMax`, `ScaleCMin`, and `ScaleCMax` determine the range of possible anisotropic scales that are exhaustively searched in the image. A scale of 1 in both scale factors corresponds to the original size of the model.

The operator `find_planar_uncalib_deformable_model` may find objects outside this range, e.g., when the object is perspectively distorted. Hence, the range parameters are a kind of suggestion for the search algorithm. Starting from this, certain models in a wider range of transformations can be detected, depending on the used pyramid levels, but also on the model/image content. It is important to note that, e.g., small scale changes can be tolerated without the need to specify a scale range, leading to faster execution times.

Often, it is not necessary to use an anisotropic scaling to find the object on the top level of the pyramid. In these cases, `ScaleCMin` and `ScaleCMax` should be set to 1. The search is then performed with isotropic scaling only, which is much faster. If the object should be detected despite severe perspective distortions anisotropic scaling is required. Here, `ScaleRMin` and `ScaleRMax` specify the anisotropic scaling in row, `ScaleCMin` and `ScaleCMax` in column direction.

Note that the transformations are treated internally such that the scalings are applied first, followed by the rotation. Therefore, the model should usually be aligned such that it appears horizontally or vertically in the model image.

Additionally, the operator `find_planar_uncalib_deformable_model` processes the parameters `'angle_step'`, `'scale_r_step'` and `'scale_c_step'` which can be set with the operator `create_planar_uncalib_deformable_model` or, as described below, with the generic parameters `GenParamName` and `GenParamValue`. In most cases, the values that can be determined automatically by `create_planar_uncalib_deformable_model` lead to good results.

The parameter `'angle_step'` determines the step size within the selected range of angles. `'angle_step'` should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence `'angle_step'` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `'angle_step'`, `'angle_step'` is modified accordingly. The parameters `'scale_r_step'` and `'scale_c_step'` determine the step size within the selected range of scales. Like `'angle_step'`, `'scale_r_step'` and `'scale_c_step'` should be chosen based on the size of the object. If the respective range of scales is not an integer multiple of `'scale_r_step'` and `'scale_c_step'`, `'scale_r_step'` and `'scale_c_step'` are modified accordingly.

MinScore: The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is. If the model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9.

NumMatches: The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0. In rare cases, `NumMatches` must be set to a higher value than the required number of matches. This is the case if, for instance, a small `MinScore` is set.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on `NumMatches`. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for `NumMatches` set to 1 might be different from the match with the highest score returned when setting `NumMatches` to 0 or > 1. If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise `NumMatches`, and then select the match with the highest score.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap` = 0, the found instances may not overlap at all, while for `MaxOverlap` = 1 all instances are returned.

GenParamName, GenParamValue: With the generic parameters `GenParamName` and `GenParamValue` it is possible to adjust parameters that typically do not have to be set by the user. By default the pose is extracted

with high subpixel accuracy (*'least_squares_very_high'*) through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. However, if no high accuracy is required by an application, the subpixel precise extraction can be reduced or switched off as it increases the processing time. Here, *'subpixel'* must be passed in `GenParamName` and *'none'*, *'least_squares'*, *'least_squares_high'* for `GenParamValue`. A further use of `GenParamName` and `GenParamValue` is to override the discretization steps of the search space *'angle_step'*, *'scale_r_step'* and *'scale_c_step'* that have been defined when the model was created in `create_planar_uncalib_deformable_model`.

As described in `create_planar_uncalib_deformable_model` the deformable matching algorithm searches exhaustively a basic set of parameters that are specified with `AngleStart`, `AngleExtent`, `ScaleRMin`, `ScaleRMax`, `ScaleCMin` and `ScaleCMax`. However, to allow a detection even when the object is imaged under perspective distortion, an additional transformation is estimated. This additional transformation transforms the model from the original search range to a bigger perspective distorted one. By allowing perspective distortions, the risk of false positives is also increased. One possible use of the parameter `GenParamName` is to help discarding false positives that occur, if for instance a small score was specified in `MinScore` and the image contains significant clutter with similar shape as the model.

To restrict arbitrary perspective matches from occurring, the values *'angle_change_restriction'* and *'aniso_scale_change_restriction'* can be used in `GenParamName`. With *'angle_change_restriction'* the maximal tolerated angular distortion can be restricted. As default value $\frac{\pi}{2}$ is set, which allows arbitrary distortion. By setting *'angle_change_restriction'* to 0, no distortion is allowed at all. The set value should be within the interval $[0, \frac{\pi}{2}]$. This parameter tests, if the angle of 90 degree at the corners of the axis-aligned rectangle around the model points is changed by more than the corresponding `GenParamValue` for the found instance of the model. Note that this parameter helps to restrict both affine (a shear mapping) and perspective parts of the transformation. As an example, with *'angle_change_restriction'* a square-like model can be prevented to match with a parallelogram or an arbitrary trapezium.

With the parameter *'aniso_scale_change_restriction'* the ratio of anisotropic scaling can be restricted (the smaller scale factor divided by the bigger scale factor). The value of this parameter ranges from the default value 0.0, where arbitrary distortion is allowed, to 1.0, where no distortion is allowed. One typical use for this parameter is to restrict for instance a square-like model to deform to a rectangular model.

NumLevels: The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the deformable model was created with `create_planar_uncalib_deformable_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_planar_uncalib_deformable_model` is used.

Greediness: The parameter `Greediness` determines how “greedily” the search should be carried out. If `Greediness` = 0, a safe search heuristic is used, which finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If `Greediness` = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For `Greediness` = 1, the maximum search speed is achieved. In almost all cases, the deformable model will be found for `Greediness` = 0.9.

Output parameters in detail

HomMat2D: The projective transformation (homographies) that encode the position of the found instances of the model are returned in `HomMat2D`. In case that multiple objects are found, the different homographies are concatenated. A single homography can easily be extracted by `tuple_select_range(HomMat2D, Index*9, (Index+1))`. The different detection results are sorted in decreasing order of `Score`. The row and column coordinates are the coordinates of the origin of the deformable model in the search image, which can be found by calling `projective_trans_pixel(HomMat2D, 0, 0, Row, Column)`. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the deformable model with `create_planar_uncalib_deformable_model`. A different origin can be set with `set_deformable_model_origin`. For visualization purposes, the model contours that are extracted by `get_deformable_model_contours` can be projected to the found location given `HomMat2D` with `projective_trans_contour_xld`.

Score: Additionally, the score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

Parameters

- ▷ **Image** (input_object)(multichannel-)image $\leadsto$ *object* : byte / uint2
Input image in which the model should be found.
- ▷ **ModelID** (input_control) deformable_model $\leadsto$ *handle*
Handle of the model.
- ▷ **AngleStart** (input_control)angle.rad $\leadsto$ *real*
Smallest rotation of the model.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ *real*
Extent of the rotation angles.
Default: 0.78
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
- ▷ **ScaleRMin** (input_control) number $\leadsto$ *real*
Minimum scale of the model in row direction.
Default: 1.0
Suggested values: ScaleRMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleRMin > 0
- ▷ **ScaleRMax** (input_control) number $\leadsto$ *real*
Maximum scale of the model in row direction.
Default: 1.0
Suggested values: ScaleRMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleRMax $\geq$ ScaleRMin
- ▷ **ScaleCMin** (input_control) number $\leadsto$ *real*
Minimum scale of the model in column direction.
Default: 1.0
Suggested values: ScaleCMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleCMin > 0
- ▷ **ScaleCMax** (input_control) number $\leadsto$ *real*
Maximum scale of the model in column direction.
Default: 1.0
Suggested values: ScaleCMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleCMax $\geq$ ScaleCMin
- ▷ **MinScore** (input_control) real $\leadsto$ *real*
Minimum score of the instances of the model to be found.
Default: 0.5
Suggested values: MinScore $\in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control)integer $\leadsto$ *integer*
Number of instances of the model to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in \{0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **MaxOverlap** (input_control)real $\leadsto$ *real*
Maximum overlap of the instances of the model to be found.
Default: 1.0
Suggested values: MaxOverlap $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumLevels** (input_control) integer(-array) $\leadsto$ *integer*
Number of pyramid levels used in the matching (and lowest pyramid level to use if |NumLevels| = 2).
Default: 0
List of values: NumLevels $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$

- ▷ **Greediness** (input_control)real $\leadsto$ real
 “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: Greediness $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{Greediness} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **GenParamName** (input_control)string-array $\leadsto$ string
 The general parameter names.
Default: []
List of values: GenParamName $\in \{[], \text{'subpixel'}, \text{'angle_change_restriction'}, \text{'aniso_scale_change_restriction'}, \text{'angle_step'}, \text{'scale_r_step'}, \text{'scale_c_step'}\}$
- ▷ **GenParamValue** (input_control)integer-array $\leadsto$ integer / real / string
 Values of the general parameters.
Default: []
List of values: GenParamValue $\in \{[], \text{'none'}, \text{'least_squares'}, \text{'least_squares_high'}, \text{'least_squares_very_high'}\}$
- ▷ **HomMat2D** (output_control)hom_mat2d(-array) $\leadsto$ real
 Homographies between model and found instances.
- ▷ **Score** (output_control)real-array $\leadsto$ real
 Score of the found instances of the model.

Result

If the parameters are valid, the operator `find_planar_uncalib_deformable_model` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

`create_planar_uncalib_deformable_model`, `read_deformable_model`

Alternatives

`find_planar_calib_deformable_model`

Module

Matching

```
get_deformable_model_contours ( : ModelContours : ModelID,
    Level : )
```

Return the contour representation of a deformable model.

The operator `get_deformable_model_contours` returns a representation of the deformable model `ModelID` as XLD contours in `ModelContours`. The parameter `Level` determines for which pyramid level of the model the contour representation should be returned. The contours can be used, for example, to visualize the found instances of the model in an image.

In case that the model was generated by `create_planar_calib_deformable_model_xld`, the contours by default are returned in the world coordinate system in metric units. Here, the contours must be transformed by the returned pose for visualizing a match.

In all other cases, the contours of the model by default are returned in the image coordinate system in pixel units. In the calibrated case this system corresponds to the rectified image coordinate system. The rectified image coordinate system is the coordinate system of an image one would obtain by `change_radial_distortion_image` when using the rectified camera parameters. The rectified camera parameters can be queried by `get_deformable_model_params`. It should be noted that the position of `ModelContours` is normalized such that the reference point of the model (see

`set_deformable_model_origin`) lies at the pixel position (0,0). Hence, the contours simply need to be transformed by the found homography in the image.

The default behavior for the calibrated case can be changed with the generic parameter 'get_deformable_model_contours_coord_system' of the operator `set_deformable_model_param`.

Parameters

- ▷ **ModelContours** (output_object) xld_cont-array $\leadsto$ *object*
Contour representation of the deformable model.
- ▷ **ModelID** (input_control) deformable_model $\leadsto$ *handle*
Handle of the model.
- ▷ **Level** (input_control) integer $\leadsto$ *integer*
Pyramid level for which the contour representation should be returned.
Default: 1
Suggested values: Level $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
Restriction: Level $\geq$ 1

Result

If the handle of the model is valid, the operator `get_deformable_model_contours` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

get_deformable_model_origin (: : ModelID : Row, Column)

Return the origin (reference point) of a deformable model.

The operator `get_deformable_model_origin` returns the origin (reference point) of the deformable model `ModelID`. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the deformable model with `create_planar_uncalib_deformable_model` or `create_planar_calib_deformable_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

Parameters

- ▷ **ModelID** (input_control) deformable_model $\leadsto$ *handle*
Handle of the model.
- ▷ **Row** (output_control) point.y $\leadsto$ *real*
Row coordinate of the origin of the deformable model.
- ▷ **Column** (output_control) point.x $\leadsto$ *real*
Column coordinate of the origin of the deformable model.

Result

If the handle of the model is valid, the operator `get_deformable_model_origin` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

<code>get_deformable_model_params</code> (: : ModelID, GenParamName : GenParamValue)
--

Return the parameters of a deformable model.

The operator `get_deformable_model_params` allows to query parameters of the deformable model. The names of the desired parameters are passed in the generic parameter `GenParamName`, the corresponding values are returned in `GenParamValue`.

The following parameters can be queried:

- '`cam_param`': Internal parameters of the camera that is used for the calibrated case.
- '`cam_param_rect`': Rectified internal parameters of the camera that is used for the calibrated case.
- '`reference_pose`': Reference position and orientation of the calibrated deformable model. The returned pose describes the model plane that the user provided.
- '`model_pose`': Reference position and orientation of the deformable model. The returned pose describes the pose of the internally used 3D metric model that was used for model generation.
- '`angle_start`': The smallest rotation angle of the model.
- '`angle_extent`': The extent of the rotation angle of the model.
- '`angle_step`': The angle step length of the model.
- '`scale_r_min`': The minimum scale of the pattern in row direction.
- '`scale_r_max`': The maximum scale of the pattern in row direction.
- '`scale_r_step`': The scale step of the pattern in row direction.
- '`scale_c_min`': The minimum scale of the pattern in column direction.
- '`scale_c_max`': The maximum scale of the pattern in column direction.
- '`scale_c_step`': The scale step of the pattern in column direction.
- '`num_levels`': User-specified number of pyramid levels.
- '`optimization`': Kind of optimization by reducing the number of model points.
- '`min_size`': Minimum size of the deformable model edge.
- '`min_contrast`': Minimum contrast of the objects in the search images.
- '`metric`': Match metric.
- '`model_row`': Row coordinate of origin in the radial undistorted model image.

'*model_col*': Column coordinate of origin in the radial undistorted model image.

'*model_type*': The type of the model: 'planar_uncalib', 'planar_calib' or 'local'.

'*created_from_xld*': Was the model created from XLD or from an image: 'created_from_xld' or 'created_from_image'.

'*get_deformable_model_contours_coord_system*': Coordinate system ('*image*' or '*world*') in which contours are returned when calling the operator [get_deformable_model_contours](#).

A detailed description of the parameters can be looked up with the operator [create_planar_uncalib_deformable_model](#) and [create_planar_calib_deformable_model](#) or with the operator [get_deformable_model_contours](#).

Note that although the parameter Contrast can be determined automatically during the model creation, its value cannot be queried using [get_deformable_model_params](#). Instead, the operator [determine_deformable_model_params](#) should be used to retrieve its value.

It is possible to query the values of several parameters with a single operator call by passing a tuple containing the names of all desired parameters to [GenParamName](#). As a result a tuple of the same length with the corresponding values is returned in [GenParamValue](#). Note that this is solely possible for parameters that return only a single value.

Parameters

- ▷ **ModelID** (input_control) deformable_model $\leadsto$ *handle*
Handle of the model.
- ▷ **GenParamName** (input_control) attribute.name(-array) $\leadsto$ *string*
Names of the generic parameters that are to be queried for the deformable model.
Default: 'angle_start'
List of values: GenParamName $\in$ {'cam_param', 'cam_param_rect', 'angle_start', 'angle_extent', 'angle_step', 'scale_r_min', 'scale_r_max', 'scale_r_step', 'scale_c_min', 'scale_c_max', 'scale_c_step', 'optimization', 'metric', 'min_contrast', 'num_levels', 'min_size', 'reference_pose', 'model_pose', 'model_row', 'model_col', 'model_type', 'created_from_xld', 'get_deformable_model_contours_coord_system'}
- ▷ **GenParamValue** (output_control) attribute.name(-array) $\leadsto$ *string* / integer / real
Values of the generic parameters.

Result

If the parameters are valid, the operator [get_deformable_model_params](#) returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

read_deformable_model (: : FileName : ModelID)

Read a deformable model from a file.

The operator `read_deformable_model` reads a deformable model from the file `FileName`, which has been written with `write_deformable_model`. The default HALCON file extension for the deformable model is 'dfm'.

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ *string*
File name.
File extension: .dfm
- ▷ **ModelID** (output_control)deformable_model $\leadsto$ *handle*
Handle of the model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

Module

Matching

serialize_deformable_model (: : ModelID : SerializedItemHandle)

Serialize a deformable model.

`serialize_deformable_model` serializes the data of a deformable model (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_deformable_model` is converted to a serialized item. The deformable model is defined by the handle `ModelID`. The serialized deformable model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_deformable_model`.

Parameters

- ▷ **ModelID** (input_control)deformable_model $\leadsto$ *handle*
Handle of a model to be saved.
- ▷ **SerializedItemHandle** (output_control)serialized_item $\leadsto$ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_deformable_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

set_deformable_model_origin (: : ModelID, Row, Column :)

Set the origin (reference point) of a deformable model.

The operator `set_deformable_model_origin` sets the origin (reference point) of the deformable model `ModelID` to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the deformable model with `create_planar_uncalib_deformable_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the deformable image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity. If a deformable model was created by `create_planar_calib_deformable_model` the 3D pose of the origin changes by the respective translation. Hence, further calls of `find_planar_calib_deformable_model` will include the pose offset. If a deformable model was created by `create_planar_calib_deformable_model_xld` the 3D pose of the origin changes directly by the offset. This means that the offsets are interpreted in world coordinates. In this case, the row coordinate corresponds to the y world coordinate (from top to down) and the column coordinate corresponds to the x world coordinate (from left to right).

Parameters

- ▷ **ModelID** (input_control) deformable_model $\leadsto$ handle
Handle of the model.
- ▷ **Row** (input_control) point.y $\leadsto$ real
Row coordinate of the origin of the deformable model.
- ▷ **Column** (input_control) point.x $\leadsto$ real
Column coordinate of the origin of the deformable model.

Result

If the handle of the model is valid, the operator `set_deformable_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

```
set_deformable_model_param ( : : ModelID, GenParamName,
                             GenParamValue : )
```

Set selected parameters of the deformable model.

The operator `set_deformable_model_param` sets the selected parameters `GenParamName` in the deformable model `ModelID`. The following parameters can be modified:

`'min_contrast'`

Sets the minimum contrast of the object in the search images for the deformable model `ModelID`. Thereby, the value of `'min_contrast'` that was originally set, e.g., with `create_planar_uncalib_deformable_model`, is overwritten for the deformable model `ModelID`. Note that if the deformable model `ModelID` was read from file and if this file should be changed as well, the deformable model `ModelID` must again be written to file after the execution of the operator `set_deformable_model_param`.

`'get_deformable_model_contours_coord_system'`

Sets the coordinate system in which the contours are returned when calling the operator `get_deformable_model_contours`. If `'world'` is passed, the contours are returned in the world coordinate system in metric units. Note that this is only possible for the calibrated case. If `'image'` is passed, the contours are returned in the image coordinate system in pixel units. In the calibrated case this system corresponds to the rectified image coordinate system. The rectified image coordinate system is the coordinate system of an image one would obtain by `change_radial_distortion_image` when using the rectified camera parameters. The rectified camera parameters can be queried by `get_deformable_model_params`. If the model was created by `create_planar_calib_deformable_model_xld` the value of `'get_deformable_model_contours_coord_system'` is `'world'` by default. In all other cases it is `'image'` by default.

Parameters

- ▷ **ModelID** (input_control) deformable_model $\leadsto$ handle
Handle of the model.
- ▷ **GenParamName** (input_control) attribute.name-array $\leadsto$ string
Parameter names.
List of values: `GenParamName` $\in$ {`'min_contrast'`, `'get_deformable_model_contours_coord_system'`}
- ▷ **GenParamValue** (input_control) attribute.value-array $\leadsto$ real / integer / string
Parameter values.
Suggested values: `GenParamValue` $\in$ {5, 6, 7, 8, 9, 10, `'image'`, `'world'`}

Result

If the parameters are valid, the operator `set_deformable_model_param` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ModelID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

`get_deformable_model_contours`, `get_deformable_model_params`

Module

Matching

```
set_local_deformable_model_metric ( Image,
    VectorField : : ModelID, Metric : )
```

Set the metric of a local deformable model that was created from XLD contours.

`set_local_deformable_model_metric` changes the value of the parameter `Metric` that was selected during the creation of the deformable model `ModelID` from XLD contours. Because no information about the polarity of the model contours is available for XLD contours, the polarity is determined based on a representative `Image`. For this, the model contours are mapped to the respective position where the object appears in the `Image`, which is done with the `VectorField` which must be of the semantic type 'vector_field_absolute' and which can be obtained by a previous call to `find_local_deformable_model`. Here, the returned `VectorField` is used for the deformable transformation. Note, that the 'expand_border' option should not be used in `find_local_deformable_model`, because then the returned `VectorField` has the wrong image size.

The parameter `Metric` then determines the conditions under which the model is recognized later in the search image. If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_local_deformable_model` will increase slightly in this case.

It must be ensured that the object contours in the `Image` have the same (or inverse) polarity as the object contours in the image in which the object must be searched later. Especially, the object must not be occluded in the `Image` and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model contour will not represent the polarity of the object contour during the search. Note that only the polarity of the contours is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multi-channel image is passed in `Image`, only the first channel will be used (and no error message will be returned).

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the model must be created from the XLD contours by setting the parameter `Metric` to 'ignore_local_polarity'. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image is provided in `VectorField`, which is of the semantic type 'vector_field_absolute'. If the matching result is correct, the value of the parameter `Metric` can be changed, e.g., to 'use_polarity'. This leads to a faster and more robust recognition in the following images.

Attention

`set_local_deformable_model_metric` can only be used with deformable models that were created from XLD contours.

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Input image used for the determination of the polarity.
- ▷ **VectorField** (input_object) singlechannelimage $\leadsto$ object : vector_field
Vector field of the local deformation.
- ▷ **ModelID** (input_control) deformable_model $\leadsto$ handle
Handle of the model.
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: `Metric` $\in$ {'use_polarity', 'ignore_global_polarity'}

Result

If the parameters are valid, the operator `set_local_deformable_model_metric` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **ModelID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

```
set_planar_calib_deformable_model_metric ( Image : : ModelID,
      Pose, Metric : )
```

Set the metric of a planar calibrated deformable model that was created from XLD contours.

`set_planar_calib_deformable_model_metric` changes the value of the parameter **Metric** that was selected during the creation of the deformable model **ModelID** from XLD contours. Because no information about the polarity of the model contours is available for XLD contours, the polarity is determined based on a representative **Image**. For this, the model contours are mapped to the respective position where the object appears in the **Image** using **Pose**, which can be obtained by a previous call to `find_planar_calib_deformable_model`.

The parameter **Metric** then determines the conditions under which the model is recognized later in the search image. If **Metric** = `'use_polarity'`, the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If **Metric** = `'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_planar_calib_deformable_model` will increase slightly in this case.

It must be ensured that the object contours in the **Image** have the same (or inverse) polarity as the object contours in the image in which the object must be searched later. Especially, the object must not be occluded in the **Image** and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model contour will not represent the polarity of the object contour during the search. Note that only the polarity of the contours is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multi-channel image is passed in **Image**, only the first channel will be used (and no error message will be returned).

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the model must be created from the XLD contours by setting the parameter **Metric** to `'ignore_local_polarity'`. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image **Pose** can be determined from the matching result. To verify the match interactively, the model contours can be mapped to this position. If the matching result is correct, the value of the parameter **Metric** can be changed, e.g., to `'use_polarity'`. This leads to a faster and more robust recognition in the following images.

Attention

`set_planar_calib_deformable_model_metric` can only be used with deformable models that were created from XLD contours.

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Input image used for the determination of the polarity.
- ▷ **ModelID** (input_control) deformable_model $\leadsto$ handle
Handle of the model.

- ▷ **Pose** (input_control) pose $\leadsto$ real / integer
Pose of the model in the image.
Number of elements: 7
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity'}

Result

If the parameters are valid, the operator `set_planar_calib_deformable_model_metric` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

set_planar_uncalib_deformable_model_metric (Image : : ModelID, HomMat2D, Metric :)
--

Set the metric of a planar uncalibrated deformable model that was created from XLD contours.

`set_planar_uncalib_deformable_model_metric` changes the value of the parameter `Metric` that was selected during the creation of the deformable model `ModelID` from XLD contours. Because no information about the polarity of the model contours is available for XLD contours, the polarity is determined based on a representative `Image`. For this, the model contours are mapped to the respective position where the object appears in the `Image` using `HomMat2D`, which can be obtained by a previous call to `find_planar_uncalib_deformable_model`.

The parameter `Metric` then determines the conditions under which the model is recognized later in the search image. If `Metric` = 'use_polarity', the object in the image and the model must have the same contrast. If, e.g., the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If `Metric` = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_planar_uncalib_deformable_model` will increase slightly in this case.

It must be ensured that the object contours in the `Image` have the same (or inverse) polarity as the object contours in the image in which the object must be searched later. Especially, the object must not be occluded in the `Image` and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model contour will not represent the polarity of the object contour during the search. Note that only the polarity of the contours is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multi-channel image is passed in `Image`, only the first channel will be used (and no error message will be returned).

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the model must be created from the XLD contours by setting the parameter `Metric` to `'ignore_local_polarity'`. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image (`HomMat2D`) can be determined from the matching result. To verify the match interactively, the model contours can be mapped to this position. If the matching result is correct, the value of the parameter `Metric` can be changed, e.g., to `'use_polarity'`. This leads to a faster and more robust recognition in the following images.

Attention

`set_planar_uncalib_deformable_model_metric` can only be used with deformable models that were created from XLD contours.

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Input image used for the determination of the polarity.
- ▷ **ModelID** (input_control) deformable_model $\leadsto$ handle
Handle of the model.
- ▷ **HomMat2D** (input_control) hom_mat2d $\leadsto$ real
Transformation matrix.
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: `'use_polarity'`
List of values: `Metric` $\in$ `{'use_polarity', 'ignore_global_polarity'}`

Result

If the parameters are valid, the operator `set_planar_uncalib_deformable_model_metric` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Matching

```
create_calib_descriptor_model ( Template : : CamParam,
    ReferencePose, DetectorType, DetectorParamName, DetectorParamValue,
    DescriptorParamName, DescriptorParamValue, Seed : ModelID )
```

Create a descriptor model for calibrated perspective matching.

The operator `create_calib_descriptor_model` prepares a descriptor model, which is used for calibrated descriptor-based matching, from a template image that is passed in `Template` (usually the domain of the image is reduced to an ROI showing only the object of interest). Note that the part of the object that is visible in the `Template` image needs to be planar.

The internal camera parameters `CamParam` and the `ReferencePose`, which describes the 3D position and orientation of the object plane shown in `Template`, are used to internally calculate a model coordinate system. The origin of this model coordinate system is obtained by projecting the center of gravity of an internally rectified version of the template image onto the object plane. The axes of the model coordinate system are built such that they are parallel to the axes of Reference Pose. To obtain a descriptor model from the template image, the points extracted by the detector in the internally rectified template image are projected onto the object plane as well. Their coordinates in the model coordinate system are stored as world coordinates in the model. This model then can be used for the pose estimation of a searched object as described with `find_calib_descriptor_model`.

A descriptor model created by the use of `create_calib_descriptor_model` can also be used in `find_uncalib_descriptor_model` to determine a homography. In contrast, it is not possible to use a model created by `create_uncalib_descriptor_model` in `find_calib_descriptor_model`.

The descriptor model describes a set of points of interest. It stores their locations and discriminative descriptions of their local gray value neighborhood. The interest point extraction is parametrized by `DetectorType`, `DetectorParamName` and `DetectorParamValue`. The respective descriptor around the interest points is parametrized by `DescriptorParamName` and `DescriptorParamValue`. The parameter `Seed` seeds the random number generator, which is used during the construction of the descriptor implemented with *randomized ferns*. The returned `ModelID` is a reference to the generated descriptor model. For further explanation on the descriptor model and its parameter we refer to the description of `create_uncalib_descriptor_model`.

The parameters and the location of the final descriptor points can be determined with `get_descriptor_model_params` and `get_descriptor_model_points`.

`create_calib_descriptor_model` stores the detector type, detector parameters and descriptor parameters, which are used in every succeeding call of `find_calib_descriptor_model` or `find_uncalib_descriptor_model`. The reference point (origin) of the model is the center of gravity of the template's ROI. Its coordinates can be changed by `set_descriptor_model_origin`.

Parameters

- ▷ **Template** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **CamParam** (input_control) campar $\leadsto$ real / integer / string
The parameters of the internal orientation of the camera.
- ▷ **ReferencePose** (input_control) pose $\leadsto$ real / integer
The reference pose of the object in the reference image.
- ▷ **DetectorType** (input_control) string $\leadsto$ string
The type of the detector.
Default: 'lepetit'
List of values: DetectorType $\in$ {'lepetit', 'harris', 'harris_binomial'}
- ▷ **DetectorParamName** (input_control) attribute.name-array $\leadsto$ string
The detector's parameter names.
Default: []
List of values: DetectorParamName $\in$ {'alpha', 'check_neighbor', 'mask_size_grd', 'mask_size_smooth', 'min_check_neighbor_diff', 'min_score', 'radius', 'sigma_grad', 'sigma_smooth', 'subpix', 'threshold'}
- ▷ **DetectorParamValue** (input_control) attribute.value-array $\leadsto$ integer / real / string
Values of the detector's parameters.
Default: []
Suggested values: DetectorParamValue $\in$ {0.08, 1, 1.2, 3, 15, 30, 1000, 'on', 'off'}

- ▷ **DescriptorParamName** (input_control) attribute.name-array $\leadsto$ *string*
 The descriptor's parameter names.
Default: []
List of values: DescriptorParamName $\in$ {'depth', 'max_rot', 'max_scale', 'min_rot', 'min_scale', 'number_ferns', 'patch_size', 'tilt'}
- ▷ **DescriptorParamValue** (input_control) attribute.value-array $\leadsto$ *integer / real / string*
 Values of the descriptor's parameters.
Default: []
Suggested values: DescriptorParamValue $\in$ {0.5, 1.4, 11, 21, 30, -180, 180, 'on', 'off'}
- ▷ **Seed** (input_control) integer $\leadsto$ *integer*
 The seed for the random number generator.
Default: 42
- ▷ **ModelID** (output_control) descriptor_model $\leadsto$ *handle*
 The handle to the descriptor model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

```
create_uncalib_descriptor_model ( Template : : DetectorType,
    DetectorParamName, DetectorParamValue, DescriptorParamName,
    DescriptorParamValue, Seed : ModelID )
```

Prepare a descriptor model for interest point matching.

The operator `create_uncalib_descriptor_model` prepares a descriptor model of an image region, which is passed in the image `Template`, that can be used for descriptor-based matching. By a subsequent call of `find_uncalib_descriptor_model` a projective 2D transformation (homography) from `Template` to a search image can be obtained. The center of gravity of the domain region in `Template` is used as an origin of the model. In contrast to `create_calib_descriptor_model`, no calibrated camera is needed and hence the result of a subsequent matching is a 2D projection. Note that the part of the object that is visible in the `Template` image needs to be planar.

The descriptor model describes a set of points of interest. It stores their locations and discriminative descriptions of their local gray value neighborhood. The interest point extraction is parametrized by `DetectorType`, `DetectorParamName` and `DetectorParamValue`. The respective descriptor around the interest points is parametrized by `DescriptorParamName` and `DescriptorParamValue`. The parameter `Seed` seeds the random number generator, which is used during the construction of the descriptor implemented with *randomized*

ferns. The returned `ModelID` is a reference to the generated descriptor model. This model can be used for an efficient detection of instances of the learned template with `find_uncalib_descriptor_model`, allowing perspective transformation between model and search image. As descriptor-based matching relies on the existence of stable and discriminative points of interest, the object to be detected must be textured, but not in a repetitive way.

Detector parameters

As mentioned, the detector is used for the extraction of stable interest points within the image. By the parameter `DetectorType`, it is possible to select the interest point operator to be used. Currently, `points_lepetit`, `points_harris`, and its binomial approximation `points_harris_binomial` are supported ('lepetit', 'harris', 'harris_binomial'). In case of templates or search images with a low contrast, one of the Harris point operators should be used. Depending on the selected `DetectorType`, appropriate parameter names and values can be set in `DetectorParamName` and `DetectorParamValue`.

Possible parameter names for `DetectorParamName` and corresponding default values are:

```
'lepetit' : ['radius', 'check_neighbor', 'min_check_neighbor_diff', 'min_score', 'subpix']
           [ 3, 1, 15, 30, 'interpolation']
'harris'   : ['sigma_grad', 'sigma_smooth', 'alpha', 'threshold']
           [0.7, 2.0, 0.08, 1000]
'harris_binomial' : ['mask_size_grd', 'mask_size_smooth', 'alpha', 'threshold', 'subpix']
           [5, 15, 0.08, 1000, 'on']
```

Further details on the meaning of those parameters can be found in the descriptions of `points_harris`, `points_harris_binomial` and `points_lepetit`, respectively. If an empty tuple is passed or a parameter is not provided in `DetectorParamName`, the above mentioned default values are taken.

While adjusting the operator parameters it should be aimed that a set of 50 to 450 feature points is extracted (depending on the texture and size of `Template`), which are uniformly distributed over the template's ROI. Therefore, it is recommended to run the point operator of choice in advance and visualize the results by `gen_cross_contour_xld`. In most cases it is sufficient to use the default setting.

Descriptor parameters

A point descriptor is a classifier, which builds characteristic descriptions of the gray-value neighborhood for interest points. Currently the descriptor is implemented with the so-called *randomized ferns*, which learns the polarity of the gray-value differences of pairs of pixels certain at *random* locations in the surrounding area of the interest point. The descriptor is later used in `find_uncalib_descriptor_model` to classify interest points in the search image, or in other words: to identify (match) potential model points in the search image.

The descriptor needs to store only the projectively *stable* interest points (which will appear in many projective views of the template). To assess the *stability* of the interest points, a simulation is performed: `Template` undergoes many affine transformations and points that can be extracted in most of the views are considered *stable*. The affine transformations are a good approximation of the projective transformations within a local neighborhood of the interest points.

The following descriptor parameters can be set with `DescriptorParamName` and `DescriptorParamValue`:

Descriptor size parameters:

'depth': depth of a classification fern. A deeper randomized fern can better discriminate interest points. However, the memory requirement for the fern grows by a factor 2 to the power of 'depth'.

Typical values are [5 ... 11], default value is 11.

'number_ferns': number of fern structures used. Using more ferns increases the recognition robustness, however it also increases the runtime of the matching. If the memory needed for the descriptor should be small, many ferns with only a small depth should be used (e.g., 'number_ferns'=150, 'depth'=5). If detection speed is more important, fewer ferns of larger depth should be used (e.g., 'number_ferns'=10, 'depth'=11).

Typical values are [1 ... 150], default value is 30.

'patch_size': side length of a quadratic neighborhood describing a point of interest. Too large values of this parameter can influence the run time.

Typical values are [15 ... 33], default value is 17.

Summing up, the parameters `'depth'`, `'number_ferns'` and `'patch_size'` allow a transparent control over detection robustness, speed and memory consumption.

Simulation parameters:

'tilt': switches on or off the projective transformations during the simulation phase. When switched on, the robustness of the model is improved and objects with bigger tilts can be found. When switched off, training time can be significantly reduced and the model is still able to recognize projectively invariant objects.

Possible values are `['on', 'off']`, default value is `'on'`.

'min_rot': minimal angle of rotation around the normal vector of `Template`.

Typical values are `[-180 ... 0]`, default value is `-180`.

'max_rot': maximal angle of rotation around the normal vector of `Template`.

Typical values are `[0 ... 180]`, default value is `180`.

'min_scale': minimal scale of `Template`.

Typical values are `[0.1 ... 1.0]`, default value is `0.5`.

'max_scale': maximal scale of `Template`.

Typical values are `[1.0 ... 3.5]`, default value is `1.4`.

The parameters `'min_rot'`, `'max_rot'`, `'min_scale'`, and `'max_scale'` allow to manually set which affine transformed views of the template are used to train the descriptor. Setting these parameters is useful to reduce training time especially in combination with the parameter `'tilt'`. Be aware that these parameters have direct influence on the results of `find_uncalib_descriptor_model` and therefore have to be set carefully. If, for example, the range of rotation is restricted from `'min_rot' = -10` to `'max_rot' = 10` it is not possible to find views of `Template` rotated by an angle outside that scope. A limited training range requires less ferns / ferns' depths to find `Template`. In such a case the number and depth of the ferns can be further reduced, which optimizes the model.

Remarks

Please note that depending on your hardware, the processing time for training the randomized ferns can vary between several seconds to some minutes. Therefore, a once trained model can be saved and loaded with `write_descriptor_model` and `read_descriptor_model`.

The parameters and the location of the final descriptor points can be determined with `get_descriptor_model_params` and `get_descriptor_model_points`.

`create_uncalib_descriptor_model` stores the detector type, detector parameters, and descriptor parameters, which are used in every succeeding call of `find_uncalib_descriptor_model`. The reference point (origin) of the model is the center of gravity of the template's ROI. Its coordinates can be changed by `set_descriptor_model_origin`.

Parameters

- ▷ **Template** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **DetectorType** (input_control) string $\leadsto$ string
The type of the detector.
Default: `'lepetit'`
List of values: `DetectorType` $\in$ `{'lepetit', 'harris', 'harris_binomial'}`
- ▷ **DetectorParamName** (input_control) attribute.name-array $\leadsto$ string
The detector's parameter names.
Default: `[]`
List of values: `DetectorParamName` $\in$ `{'alpha', 'check_neighbor', 'mask_size_grd', 'mask_size_smooth', 'min_check_neighbor_diff', 'min_score', 'radius', 'sigma_grad', 'sigma_smooth', 'subpix', 'threshold'}`
- ▷ **DetectorParamValue** (input_control) attribute.value-array $\leadsto$ integer / real / string
Values of the detector's parameters.
Default: `[]`
Suggested values: `DetectorParamValue` $\in$ `{0.08, 1, 1.2, 3, 15, 30, 1000, 'on', 'off', 'none', 'interpolation'}`
- ▷ **DescriptorParamName** (input_control) attribute.name-array $\leadsto$ string
The descriptor's parameter names.
Default: `[]`
List of values: `DescriptorParamName` $\in$ `{'depth', 'max_rot', 'max_scale', 'min_rot', 'min_scale', 'number_ferns', 'patch_size', 'tilt'}`

- ▷ **DescriptorParamValue** (input_control) attribute.value-array $\leadsto$ integer / real / string
Values of the descriptor's parameters.
Default: []
Suggested values: DescriptorParamValue $\in$ {0.5, 1.4, 11, 21, 30, -180, 180, 'on', 'off'}
- ▷ **Seed** (input_control) integer $\leadsto$ integer
The seed for the random number generator.
Default: 42
- ▷ **ModelID** (output_control) descriptor_model $\leadsto$ handle
The handle to the descriptor model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

```
deserialize_descriptor_model (
    :   :   SerializedItemHandle :   ModelID )
```

Deserialize a descriptor model.

`deserialize_descriptor_model` deserializes a descriptor model, that was serialized by [serialize_descriptor_model](#) (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The serialized descriptor model is defined by the handle [SerializedItemHandle](#). The deserialized values are stored in an automatically created descriptor model with the handle [ModelID](#).

Parameters

- ▷ **SerializedItemHandle** (input_control) serialized_item $\leadsto$ handle
Handle of the serialized item.
- ▷ **ModelID** (output_control) descriptor_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `deserialize_descriptor_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

Matching

```
find_calib_descriptor_model ( Image : : ModelID,
    DetectorParamName, DetectorParamValue, DescriptorParamName,
    DescriptorParamValue, MinScore, NumMatches, CamParam,
    ScoreType : Pose, Score )
```

Find the best matches of a calibrated descriptor model in an image and return their 3D pose.

The operator `find_calib_descriptor_model` finds the best `NumMatches` matches of the descriptor model `ModelID` in `Image`. The descriptor model must have been created previously by calling `create_calib_descriptor_model` or `read_descriptor_model`.

The operator returns the 3D `Pose` (in camera coordinate system) of the template object found in the search `Image`. As two different cameras can be used for the model generation and the online search, the camera parameters of the camera used to create `Image` have to be set in `CamParam`.

The detection process is the same as for `find_uncalib_descriptor_model`. The setting of `DetectorParamName`, `DetectorParamValue`, `DescriptorParamName`, `DescriptorParamValue`, `MinScore`, `NumMatches` and `ScoreType` are explained with `find_uncalib_descriptor_model`. After the object was detected, and using the world (from reference plane) coordinates of the matched model points (explained with `create_calib_descriptor_model`), the pose of the object is computed similarly to applying `vector_to_pose` operator.

The point correspondences for each object can be queried with `get_descriptor_model_points`.

Attention

Note that the domain of the search image should contain the whole object to be searched for because interest points are only extracted inside the domain of the search image. This means that if the domain does not contain the full object to be searched for, the resulting `Score` will decrease. Note also that matches may be found even if the reference point (origin) of the model lies outside of the domain of the search image. Both is in contrast to shape-based matching, where the domain of the search image defines the search space for the reference point of the model.

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ *object* : byte / uint2
Input image where the model should be found.
- ▷ **ModelID** (input_control) descriptor_model $\leadsto$ *handle*
The handle to the descriptor model.
- ▷ **DetectorParamName** (input_control) attribute.name-array $\leadsto$ *string*
The detector's parameter names.
Default: []
List of values: `DetectorParamName` $\in$ { 'alpha', 'check_neighbor', 'mask_size_grd', 'mask_size_smooth', 'min_check_neighbor_diff', 'min_score', 'radius', 'sigma_grad', 'sigma_smooth', 'subpix', 'threshold' }
- ▷ **DetectorParamValue** (input_control) attribute.value-array $\leadsto$ *integer* / *real* / *string*
Values of the detector's parameters.
Default: []
Suggested values: `DetectorParamValue` $\in$ { 0.08, 1, 1.2, 3, 15, 30, 1000, 'on', 'off' }

- ▷ **DescriptorParamName** (input_control) attribute.name-array $\leadsto$ string
The descriptor's parameter names.
Default: []
List of values: DescriptorParamName $\in$ {'min_score_descr', 'guided_matching'}
- ▷ **DescriptorParamValue** (input_control) attribute.value-array $\leadsto$ real / integer / string
Values of the descriptor's parameters.
Default: []
Suggested values: DescriptorParamValue $\in$ {0.0, 0.001, 0.005, 0.01, 'on', 'off'}
- ▷ **MinScore** (input_control) real(-array) $\leadsto$ real
Minimum score of the instances of the models to be found.
Default: 0.2
Suggested values: MinScore $\in$ {0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{MinScore} \leq 1$
- ▷ **NumMatches** (input_control) integer $\leadsto$ integer
Maximal number of found instances.
Default: 1
Suggested values: NumMatches $\in$ {1, 2, 3, 4}
Restriction: NumMatches ≥ 1
- ▷ **CamParam** (input_control) campar $\leadsto$ real / integer / string
Camera parameter (inner orientation) obtained from camera calibration.
- ▷ **ScoreType** (input_control) string(-array) $\leadsto$ string
Score type to be evaluated in [Score](#).
Default: 'num_points'
List of values: ScoreType $\in$ {'num_points', 'inlier_ratio'}
- ▷ **Pose** (output_control) pose(-array) $\leadsto$ real / integer
3D pose of the object.
- ▷ **Score** (output_control) number(-array) $\leadsto$ real / integer
Score of the found instances according to the ScoreType input.

Example

```
* Perform camera calibration (with standard calibration plate)
calibrate_cameras (CalibDataID, Error)
get_calib_data (CalibDataID, 'camera', 0, 'params', CamParam)
* World coordinate system is defined by calibration plate in first image
get_calib_data (CalibDataID, 'calib_obj_pose', [0,0], 'pose', \
                ObjInCameraPose)
* Compensate thickness of plate
set_origin_pose (ObjInCameraPose, 0, 0, 0.0006, WorldPose)

* Create descriptor model:
create_calib_descriptor_model (Image, CamParam, WorldPose, \
                              'harris', [], [], [], [], 42, ModelID)

get_descriptor_model_params (ModelID, DetectorType, \
                            DetectorParamName, DetectorParamValue, \
                            DescriptorParamName, DescriptorParamValue)
write_descriptor_model (ModelID, 'simple_example.dsm')

read_descriptor_model ('simple_example.dsm', ModelID)
find_calib_descriptor_model (SearchImage, ModelID, [], [], [], [], 0.2, 1, \
                            CamParam, ['num_points', 'inlier_ratio'], \
                            Pose, Score)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

Matching

```
find_uncalib_descriptor_model ( Image : : ModelID,
    DetectorParamName, DetectorParamValue, DescriptorParamName,
    DescriptorParamValue, MinScore, NumMatches, ScoreType : HomMat2D,
    Score )
```

Find the best matches of a descriptor model in an image.

The operator `find_uncalib_descriptor_model` finds the best matches of a descriptor model `ModelID` in `Image`. The descriptor model must have been created previously by calling `create_uncalib_descriptor_model`, `create_calib_descriptor_model` or `read_descriptor_model`.

A match is only accepted if its score exceeds the value of `MinScore`. This criterion is based on the 'inlier_ratio' score that is described in details below. The main result of the operator `find_uncalib_descriptor_model` for each match is a 3x3 matrix `HomMat2D`, which describes a 2D projection of model points to search image points and is represented by a tuple of 9 elements in row-major order. If more matches of the searched object (template) appear and pass the `MinScore` criterion, the resulting multiple homographies are concatenated. The number of objects actually found is then equal to `NumObjects = |HomMat2D|/9`.

The detection process is divided into three parts. **First**, interest points are extracted from the search image (only inside the domain of the search image). This is done using the point detector and its parameters selected once during the generation of the model. However, `DetectorParamName` and `DetectorParamValue` can be used to specify different detector parameter values during the `find_uncalib_descriptor_model` call. By changing these parameters, it is possible to adjust to illumination changes between the model generation and the online detection. However, it is recommended to use the same values used to create the model (pass an empty tuple).

The second step of the detection process is to calculate correspondences between the model points and the points that were detected. The run time parameters of the descriptor can be adjusted with `DescriptorParamName` and `DescriptorParamValue`:

`'min_score_descr'`: is the minimal classifier score for an interest point to be regarded as a potential match. The score function is between 0.0 and 1.0, but typically only values between 0.0 and 0.1 make sense. Increasing `'min_score_descr'` can increase significantly the detection speed. Note, however, that using `'min_score_descr'` might have negative effect on the robustness of the detection process, especially when only few points can be found.
Typical values are `[0.0 ... 0.1]`, default value is `0.0`.

`'guided_matching'`: enhances the accuracy of the object recognition when switched on. Note that it increases the computational costs up to 10% in some cases.
Possible values are `['on', 'off']`, default value is `'on'`.

The last step is the estimation of a homography that describes the point correspondences. The homography is a 2D projection, which describes a transformation from model points to points in `Image`. Here, Natural 3D Markers (N3Ms) are utilized to identify robustly the point correspondences (see references).

Additionally to the estimated homography in `HomMat2D`, the operator returns one or more `Score` estimations per object instance as specified by the user in a tuple `ScoreType`. Currently the following values for `ScoreType` are supported:

`'num_points'`: number of point correspondences per instance. An object instance should be considered good, if it has 10 or more point correspondences with the model. Fewer points are insufficient, because any random 4 point correspondences define a mathematically correct homography between two images.

'*inlier_ratio*': the ratio of the number of point correspondences to the number of model points. Although this value can have values of $[0.0 \dots 1.0]$, it is rather unlikely that this ratio can reach 1.0 . Yet, objects having inlier ratio less than 0.1 , should be disregarded.

Note that the resulting scores for more than one object instance will be concatenated in `Score`, such that `lScore = NumObjects * lScoreType`.

The point correspondences for each object can be queried with `get_descriptor_model_points`.

Attention

Note that the domain of the search image should contain the whole object to be searched for because interest points are only extracted inside the domain of the search image. This means that if the domain does not contain the full object to be searched for, the resulting `Score` will decrease. Note also that matches may be found even if the reference point (origin) of the model lies outside of the domain of the search image. Both is in contrast to shape-based matching, where the domain of the search image defines the search space for the reference point of the model.

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Input image where the model should be found.
- ▷ **ModelID** (input_control) descriptor_model $\leadsto$ handle
The handle to the descriptor model.
- ▷ **DetectorParamName** (input_control) attribute.name-array $\leadsto$ string
The detector's parameter names.
Default: []
List of values: DetectorParamName $\in$ {'alpha', 'check_neighbor', 'mask_size_grd', 'mask_size_smooth', 'min_check_neighbor_diff', 'min_score', 'radius', 'sigma_grad', 'sigma_smooth', 'subpix', 'threshold'}
- ▷ **DetectorParamValue** (input_control) attribute.value-array $\leadsto$ integer / real / string
Values of the detector's parameters.
Default: []
Suggested values: DetectorParamValue $\in$ {0.08, 1, 1.2, 3, 15, 30, 1000, 'on', 'off'}
- ▷ **DescriptorParamName** (input_control) attribute.name-array $\leadsto$ string
The descriptor's parameter names.
Default: []
List of values: DescriptorParamName $\in$ {'min_score_descr', 'guided_matching'}
- ▷ **DescriptorParamValue** (input_control) attribute.value-array $\leadsto$ real / integer / string
Values of the descriptor's parameters.
Default: []
Suggested values: DescriptorParamValue $\in$ {0.0, 0.001, 0.005, 0.01, 'on', 'off'}
- ▷ **MinScore** (input_control) real(-array) $\leadsto$ real
Minimum score of the instances of the models to be found.
Default: 0.2
Suggested values: MinScore $\in$ {0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{MinScore} \leq 1$
- ▷ **NumMatches** (input_control) integer $\leadsto$ integer
Maximal number of found instances.
Default: 1
Suggested values: NumMatches $\in$ {1, 2, 3, 4}
Restriction: NumMatches ≥ 1
- ▷ **ScoreType** (input_control) string(-array) $\leadsto$ string
Score type to be evaluated in `Score`.
Default: 'num_points'
List of values: ScoreType $\in$ {'num_points', 'inlier_ratio'}
- ▷ **HomMat2D** (output_control) hom_mat2d(-array) $\leadsto$ real
Homography between model and found instance.
- ▷ **Score** (output_control) number(-array) $\leadsto$ real / integer
Score of the found instances according to the ScoreType input.

Example

```
create_uncalib_descriptor_model (ImageReduced, 'harris', [], [], \
                                [], [], 42, ModelID)

get_descriptor_model_params (ModelID, DetectorType, \
                             DetectorParamName, DetectorParamValue, \
                             DescriptorParamName, DescriptorParamValue)

write_descriptor_model (ModelID, 'simple_example.dsm')

read_descriptor_model ('simple_example.dsm', ModelID)

find_uncalib_descriptor_model (SearchImage, ModelID, [], [], [], [], 0.2, 1, \
                               ['num_points', 'inlier_ratio'], HomMat2D, Score)
```

Execution Information

Module

Matching

get_descriptor_model_origin (: : ModelID : Row, Column)
--

Return the origin of a descriptor model.

The operator `get_descriptor_model_origin` returns the origin (reference point) of the descriptor model `ModelID`. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the descriptor model with [create_uncalib_descriptor_model](#), or [create_calib_descriptor_model](#). Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

Parameters

- ▷ **ModelID** (input_control) descriptor_model $\leadsto$ handle
Handle of a descriptor model.
- ▷ **Row** (output_control) real $\leadsto$ real / integer
Position of origin in row direction.
- ▷ **Column** (output_control) real $\leadsto$ real / integer
Position of origin in column direction.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

Matching

```
get_descriptor_model_params ( : : ModelID : DetectorType,
    DetectorParamName, DetectorParamValue, DescriptorParamName,
    DescriptorParamValue )
```

Return the parameters of a descriptor model.

The operator `get_descriptor_model_params` allows to access the parameters of a descriptor model that was created with [create_uncalib_descriptor_model](#) or [create_calib_descriptor_model](#). Therefore, a handle of a descriptor model must be passed in `ModelID`. The operator returns in `DetectorType`, `DetectorParamName` and `DetectorParamValue` the type and parametrization of the detector. In `DescriptorType`, `DescriptorParamName` and `DescriptorParamValue` the respective descriptor is returned.

An application for this operator is the possibility to query the parameters that were used in a stored model. As the operator needs a handle to a descriptor model, it has to be loaded first by using [read_descriptor_model](#).

Parameters

- ▷ **ModelID** (input_control)descriptor_model $\leadsto$ *handle*
The object handle to the descriptor model.
- ▷ **DetectorType** (output_control) string $\leadsto$ *string*
The type of the detector.
- ▷ **DetectorParamName** (output_control) attribute.name-array $\leadsto$ *string*
The detectors parameter names.
- ▷ **DetectorParamValue** (output_control) attribute.value-array $\leadsto$ *integer / real / string*
Values of the detectors parameters.
- ▷ **DescriptorParamName** (output_control) attribute.name-array $\leadsto$ *string*
The descriptors parameter names.
- ▷ **DescriptorParamValue** (output_control) attribute.value-array $\leadsto$ *integer / real / string*
Values of the descriptors parameters.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[create_uncalib_descriptor_model](#), [create_calib_descriptor_model](#)

Module

Matching

```
get_descriptor_model_points ( : : ModelID, Set, Subset : Row,
    Column )
```

Query the interest points of the descriptor model or the last processed search image.

With the operator `get_descriptor_model_points` interest points of the descriptor model or the last processed search image can be queried. It requires a `ModelID` returned by `create_uncalib_descriptor_model`, `create_calib_descriptor_model`, or `read_descriptor_model`.

The interest points stored in the model can always be queried by setting `Set` to `'model'` and `Subset` to `'all'`. If a `find_uncalib_descriptor_model` or `find_calib_descriptor_model` precedes, with `get_descriptor_model_points` the interest points of the last search image can be queried as well by setting `Set` to `'search'` and `Subset` to `'all'`. Additionally, the matched (corresponding) points for each object instance found can be queried by setting `Set` to `'model'` or `'search'` (for the correspondences on the model or search image side, respectively) and `Subset` to the result number of the instance. The image coordinates of the queried points are returned in `Row` and `Column`.

Parameters

- ▷ **ModelID** (input_control)descriptor_model $\leadsto$ handle
The handle to the descriptor model.
 - ▷ **Set** (input_control)string $\leadsto$ string
Set of interest points.
Default: `'model'`
List of values: `Set` $\in$ `{'model', 'search'}`
 - ▷ **Subset** (input_control) integer $\leadsto$ integer / string
Subset of interest points.
Default: `'all'`
Suggested values: `Subset` $\in$ `{'all', 0, 1, 2}`
 - ▷ **Row** (output_control)point.y-array $\leadsto$ real / integer
Row coordinates of interest points.
 - ▷ **Column** (output_control) point.x-array $\leadsto$ real / integer
Column coordinates of interest points.
-

Example

```
create_uncalib_descriptor_model (Template, 'harris', [], [], [], [], 42, \
                                ModelID)
* Model points can be queried from a model, even if just created
get_descriptor_model_points (ModelID, 'model', 'all', ModelRow, ModelColumn)
find_uncalib_descriptor_model (Image, ModelID, [], [], [], [], 0.2, 1, \
                                'num_points', HomMat2D, Score)
* Search points can be queried only after a
* find_[un]calib_descriptor_model was executed
get_descriptor_model_points (ModelID, 'search', 'all', SearchRow, SearchColumn)
* Additionally, correspondences for the results can be queried
NumObjects := |HomMat2D|/9
for I := 0 to NumObjects-1 by 1
    * Query corresponding points in the model
    get_descriptor_model_points (ModelID, 'model', I, \
                                CorrModelRow, CorrModelColumn)
    * Query corresponding points in the search image
    get_descriptor_model_points (ModelID, 'search', I, \
                                CorrSearchRow, CorrSearchColumn)
    * Those points are typically for visualizational purposes
    gen_cross_contour_xld (CrossModel, CorrModelRow, CorrModelColumn, \
                           6, 0.78)
    gen_cross_contour_xld (CrossSearch, CorrSearchRow, CorrSearchColumn, \
                           6, 0.78)

    * ....
endfor
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

`create_uncalib_descriptor_model`, `create_calib_descriptor_model`

Module

Matching

get_descriptor_model_results (: : ModelID, ObjectID,
ResultNames : Results)

Query alphanumerical results that were accumulated during descriptor-based matching.

The operator `get_descriptor_model_results` allows to access alphanumeric results of the descriptor based matching process. The results are stored in a descriptor based model specified by `ModelID`. `ObjectID` specifies for which object the results should be returned. The objects are 0-based indexed and in the same order as they are detected by `find_uncalib_descriptor_model` or `find_calib_descriptor_model`, respectively. Results can be queried for all objects at once by specifying 'all' in `ObjectID`, if they are single valued (e.g., `ResultNames='num_points'` or `ResultNames='inlier_ratio'`).

The results returned in `Results` can be selected by setting `ResultNames` to:

'num_points': number of object points that correspond to model points.

'inlier_ratio': ratio of successfully matched object points relative to all descriptor model points.

'homography': a 3x3 projective transformation matrix which transforms model points into object points. Note that the result of the mapping depends on the selected model origin (see `set_descriptor_model_origin`).

'pose': returns the estimated object pose. Note that this result can only be queried after `find_calib_descriptor_model` was called.

'point_classification': returns concatenated triads representing the classification results for the interest points extracted from the search image during the last call of `find_uncalib_descriptor_model` or `find_calib_descriptor_model`. Each triad consists of a *search point index* on the first, a *model point index* on the second, and a *classification score* on the third position. The search and model point indices correspond to the point coordinates returned by `get_descriptor_model_points` with the parameter `Subset` set to 'all' and the parameter `Set` set to 'search' and 'model', respectively. If a number is passed in `ObjectID` only the classification results for the points matched to this object are returned. If 'all' is passed in `ObjectID` the classification results for all points, including the points not matched to any object, are returned. The triads are sorted in descending order with respect to their score. Points having a score less than the value of the descriptor parameter 'min_score_descr' (see `find_calib_descriptor_model` or `find_uncalib_descriptor_model`) are rejected and are not listed in the resulting classification results.

Parameters

- ▷ **ModelID** (input_control)descriptor_model $\leadsto$ handle
Handle of a descriptor model.
- ▷ **ObjectID** (input_control)integer $\leadsto$ integer / string
Handle of the object for which the results are queried.
Default: 'all'
Suggested values: `ObjectID` $\in$ {'all', 0, 1, 2, 3}

- ▷ **ResultNames** (input_control) attribute.name $\leadsto$ *string*
 Name of the results to be queried.
Default: 'num_points'
List of values: ResultNames $\in$ {'num_points', 'inlier_ratio', 'homography', 'pose', 'point_classification'}
- ▷ **Results** (output_control) attribute.value(-array) $\leadsto$ *string* / integer / real
 Returned results.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

read_descriptor_model (: : FileName : ModelID)

Read a descriptor model from a file.

The operator `read_descriptor_model` reads a descriptor model, which has been written with [write_descriptor_model](#), from the file `FileName`. The default HALCON file extension for the descriptor model is 'dsm'.

Parameters

- ▷ **FileName** (input_control) filename.read $\leadsto$ *string*
 File name.
File extension: .dsm
- ▷ **ModelID** (output_control) descriptor_model $\leadsto$ *handle*
 Handle of the model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

[create_calib_descriptor_model](#), [create_uncalib_descriptor_model](#)

Module

Matching

serialize_descriptor_model (: : ModelID : SerializedItemHandle)

Serialize a descriptor model.

`serialize_descriptor_model` serializes the data of a descriptor model (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The same data that is written in a file by `write_descriptor_model` is converted to a serialized item. The descriptor model is defined by the handle `ModelID`. The serialized descriptor model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_descriptor_model`.

Parameters

- ▷ **ModelID** (input_control)descriptor_model $\leadsto$ handle
Handle of a model to be saved.
- ▷ **SerializedItemHandle** (output_control)serialized_item $\leadsto$ handle
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_descriptor_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

set_descriptor_model_origin (: : ModelID, Row, Column :)

Sets the origin of a descriptor model.

The operator `set_descriptor_model_origin` sets the origin (reference point) of the descriptor model `ModelID` to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the descriptor model with [create_uncalib_descriptor_model](#), or [create_calib_descriptor_model](#). Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity. The new setting affects the succeeding [find_uncalib_descriptor_model](#) and [find_calib_descriptor_model](#) calls.

Parameters

- ▷ **ModelID** (input_control)descriptor_model $\leadsto$ handle
Handle of a descriptor model.
- ▷ **Row** (input_control) real $\leadsto$ real / integer
Translation of origin in row direction.
Default: 0
- ▷ **Column** (input_control) real $\leadsto$ real / integer
Translation of origin in column direction.
Default: 0

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

write_descriptor_model (: : ModelID, FileName :)

Write a descriptor model to a file.

The operator `write_descriptor_model` writes a descriptor model to the file `FileName`. The model can be read again with [read_descriptor_model](#). The default HALCON file extension for the descriptor model is 'dsm'.

Parameters

- ▷ **ModelID** (input_control)descriptor_model $\leadsto$ *handle*
Handle of a model to be saved.
- ▷ **FileName** (input_control)filename.write $\leadsto$ *string*
The path and filename of the model to be saved.
File extension: .dsm

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

18.6 Shape-Based

adapt_shape_model_high_noise (ImageReduced : : ModelID, GenParam : ResultDict)
--

Adapt a shape model's parameters for high noise images.

`adapt_shape_model_high_noise` adapts the parameters of a shape model `ModelID` for high noise images and returns them in `ResultDict`. Based on a sample search image `ImageReduced`, the optimal values of the shape model's parameters are estimated and adapted in the model. The domain of `ImageReduced` should contain the model and surrounding background, such that the typical noise is presented to the algorithm. With [GenParam](#)

the parameters to be estimated can be controlled. Currently, the operator supports the estimation of the lowest pyramid level used in the matching step. Accordingly, the value `'all'` or `'lowest_level'` should be provided to `GenParam`.

Note: The operator changes the shape model `ModelID` by setting the estimated lowest pyramid level.

Parameters

- ▷ **ImageReduced** (input_object) (multichannel-)image $\leadsto$ object : byte / uint2
Sample search image with reduced domain.
- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the shape model.
- ▷ **GenParam** (input_control) string-array $\leadsto$ string
Parameters to be estimated.
Default: `'all'`
List of values: `GenParam` $\in$ `{'lowest_level', 'all'}`
- ▷ **ResultDict** (output_control) dict $\leadsto$ handle
Dictionary with the estimated parameter values.

Result

If the parameters are valid, the operator `adapt_shape_model_high_noise` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators. This operator modifies the state of the following input parameter:

- `ModelID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_generic_shape_model`

Possible Successors

`find_generic_shape_model`

Module

Matching

clear_shape_model (: : ModelID :)

Free the memory of a shape model.

The operator `clear_shape_model` frees the memory of a shape model that was created by `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`. After calling `clear_shape_model`, the model can no longer be used. The handle `ModelID` becomes invalid.

Parameters

- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.

Result

If the handle of the model is valid, the operator `clear_shape_model` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Matching	

```
create_aniso_shape_model ( Template : : NumLevels, AngleStart,
    AngleExtent, AngleStep, ScaleRMin, ScaleRMax, ScaleRStep,
    ScaleCMin, ScaleCMax, ScaleCStep, Optimization, Metric, Contrast,
    MinContrast : ModelID )
```

Prepare an anisotropically scaled shape model for matching.

The operator `create_aniso_shape_model` prepares a template, which is passed in the image `Template`, as an anisotropically scaled shape model used for matching. The ROI of the model is passed as the domain of `Template`.

The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_aniso_shape_model`. The center of gravity of the domain (region) of the model image `Template` is used as the origin (reference point) of the model. A different origin can be set with `set_shape_model_origin`. The model is generated using multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations and anisotropic scales (i.e., independent scales in the row and column direction) on each level. The model can be extended by clutter parameters with `set_shape_model_clutter`.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. This can be checked using the output of `inspect_shape_model`. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_aniso_shape_model` returns with an error message.

If `NumLevels` is set to 'auto' (or 0 for backwards compatibility), `create_aniso_shape_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_aniso_shape_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greedyiness` in `find_aniso_shape_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_aniso_shape_model` may increase. In these cases, the number of pyramid levels should be selected using the output of `inspect_shape_model`.

AngleStart, AngleExtent, and AngleStep: The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by `find_aniso_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_aniso_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_aniso_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller

models do not have many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly.

To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_aniso_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value n such that `AngleStart` plus n times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax, ScaleRStep, and ScaleCStep: The parameters `ScaleRMin`, `ScaleRMax`, `ScaleCMin`, and `ScaleCMax` determine the range of possible anisotropic scales of the model in the row and column direction. A scale of 1 in both scale factors corresponds to the original size of the model. The parameters `ScaleRStep` and `ScaleCStep` determine the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in `find_aniso_shape_model`, these parameters specify the accuracy that is achievable for the scales in `find_aniso_shape_model`. Like `AngleStep`, `ScaleRStep` and `ScaleCStep` should be chosen based on the size of the object. If the respective range of scales is not an integer multiple of `ScaleRStep` and `ScaleCStep`, `ScaleRStep` and `ScaleCStep` are modified accordingly.

To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by `find_aniso_shape_model`, the range of possible scales is modified as follows: If there are no positive integer values n and m such that `ScaleRMin` plus n times `ScaleRStep` is exactly 1.0 and `ScaleCMin` plus m times `ScaleCStep` is exactly 1.0, `ScaleRMin` and `ScaleCMin` are decreased by up to `ScaleRStep` and `ScaleCStep`, respectively, and `ScaleRMax` and `ScaleCMax` are increased such that the range of possible scales is increased by `ScaleRStep` and `ScaleCStep`, respectively.

Note that the transformations are treated internally such that the scalings are applied first, followed by the rotation. Therefore, the model should usually be aligned such that it appears horizontally or vertically in the model image.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from 'none'. If `Optimization` = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_aniso_shape_model` to set the parameter `Greediness` to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to 'auto', `create_aniso_shape_model` automatically determines the reduction of the number of model points.

Metric: The parameter `Metric` determines the conditions under which the model is recognized in the image.

If `Metric` = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric` = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_aniso_shape_model` will increase slightly in this case.

If `Metric` = 'ignore_local_polarity', the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_aniso_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_aniso_shape_model`, and to match them simultaneously with `find_aniso_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If `Metric` = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_aniso_shape_model` can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'. It should be noted that for `Metric` = 'ignore_color_polarity' the number of channels in the model creation with `create_aniso_shape_model` and in the search with

`find_aniso_shape_model` can be different. This can, for example, be used to create a model from a synthetically generated single-channel image. Furthermore, it should be noted that the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Contrast: The parameter `Contrast` determines the contrast the model points must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. `Contrast` should be chosen such that only the significant features of the template are used for the model. `Contrast` can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see `hysteresis_threshold`. Optionally, `Contrast` can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in `Contrast`. In this case, the first two values can simply be set to identical values. The effect of this parameter can be checked in advance with `inspect_shape_model`.

If `Contrast` is set to `'auto'`, `create_aniso_shape_model` determines the three above described values automatically. Besides, only the contrast (`'auto_contrast'`), the hysteresis thresholds (`'auto_contrast_hyst'`), or the minimum size (`'auto_min_size'`) can be determined automatically. The remaining values that are not determined automatically can additionally be passed in the form of a tuple. Also various combinations are allowed: If, for example, [`'auto_contrast'`, `'auto_min_size'`] is passed, both the contrast and the minimum size are determined automatically. If [`'auto_min_size'`, 20, 30] is passed, the minimum size is determined automatically while the hysteresis thresholds are set to 20 and 30, etc. In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with `determine_shape_model_params` and subsequently verified using `inspect_shape_model` before calling `create_aniso_shape_model`. Note that `MinContrast` influences the automatic contrast estimation, and hence also the estimation of the minimum size.

MinContrast: With `MinContrast`, it can be determined which contrast the model must at least have in the recognition performed by `find_aniso_shape_model`. In other words, this parameter separates the model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, `MinContrast` should be set to 10. If multichannel images are used for the model and the search images, and if the parameter `Metric` is set to `'ignore_color_polarity'` (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine `MinContrast`. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image `MinContrast` should be set to 17. Obviously, `MinContrast` must be smaller than `Contrast`. If the model should be recognized in very low contrast images, `MinContrast` must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, `MinContrast` should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by `find_aniso_shape_model`.

If `MinContrast` is set to `'auto'`, the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using `get_shape_model_params`.

Complete pregeneration of the model

Optionally, a second value can be passed in `Optimization`. This value determines whether the model is pre-generated completely or not. To do so, the second value of `Optimization` must be set to either `'pregeneration'` or `'no_pregeneration'`. If the second value is not used (i.e., if only one value is passed), the mode that is set with `set_system('pregenerate_shape_models', ...)` is used. With the default value (`'pregenerate_shape_models' = 'false'`), the model is not pregenerated completely. The complete pregeneration of the model

normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, `find_aniso_shape_model` typically returns slightly lower scores, which may require setting a slightly lower value for `MinScore` than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if `AngleStep`, `ScaleRStep`, or `ScaleCStep` are too small or `AngleExtent` or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, `AngleStep`, `ScaleRStep`, or `ScaleCStep` must be enlarged or `AngleExtent` or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by `find_aniso_shape_model`, `AngleStep` $\geq 1^\circ$ and `ScaleRStep`, `ScaleCStep` ≥ 0.02 can be selected for models of a diameter smaller than about 200 pixels.

If `AngleStep` = 'auto' or `ScaleRStep`, `ScaleCStep` = 'auto' (or 0 for backwards compatibility in both cases) is selected, `create_aniso_shape_model` automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using `get_shape_model_params`.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in `find_aniso_shape_model`. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

Parameters

- ▷ **Template** (input_object) (multichannel-)image $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the pattern.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in$ {6.29, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtent ≥ 0
- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ real / string
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep ≥ 0 && AngleStep $\leq \pi / 2$
- ▷ **ScaleRMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in the row direction.
Default: 0.9
Suggested values: ScaleRMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleRMin > 0

- ▷ **ScaleRMax** (input_control) number $\leadsto$ real
Maximum scale of the pattern in the row direction.
Default: 1.1
Suggested values: ScaleRMax $\in$ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
Restriction: ScaleRMax $\geq$ ScaleRMin
- ▷ **ScaleRStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in the row direction.
Default: 'auto'
Suggested values: ScaleRStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleRStep $\geq$ 0
- ▷ **ScaleCMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern in the column direction.
Default: 0.9
Suggested values: ScaleCMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleCMin $>$ 0
- ▷ **ScaleCMax** (input_control) number $\leadsto$ real
Maximum scale of the pattern in the column direction.
Default: 1.1
Suggested values: ScaleCMax $\in$ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
Restriction: ScaleCMax $\geq$ ScaleCMin
- ▷ **ScaleCStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in the column direction.
Default: 'auto'
Suggested values: ScaleCStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleCStep $\geq$ 0
- ▷ **Optimization** (input_control) string(-array) $\leadsto$ string
Kind of optimization and optionally method used for generating the model.
Default: 'auto'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high', 'pregeneration', 'no_pregeneration'}
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **Contrast** (input_control) number(-array) $\leadsto$ integer / string
Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
Default: 'auto'
Suggested values: Contrast $\in$ {'auto', 'auto_contrast', 'auto_contrast_hyst', 'auto_min_size', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer / string
Minimum contrast of the objects in the search images.
Default: 'auto'
Suggested values: MinContrast $\in$ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}
Restriction: MinContrast $<$ Contrast
- ▷ **ModelID** (output_control) shape_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_aniso_shape_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameters `NumLevels` and `Contrast` are chosen such that the model contains too few points, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

```
create_aniso_shape_model_xld ( Contours : : NumLevels,
    AngleStart, AngleExtent, AngleStep, ScaleRMin, ScaleRMax,
    ScaleRStep, ScaleCMin, ScaleCMax, ScaleCStep, Optimization,
    Metric, MinContrast : ModelID )
```

Prepare an anisotropically scaled shape model for matching from XLD contours.

The operator `create_aniso_shape_model_xld` creates an anisotropically scaled shape model used for matching from the XLD contours passed in `Contours`. The XLD contours represent the gray value edges of the object to be searched for. In contrast to the operator `create_aniso_shape_model`, which creates a shape model from a template image, the operator `create_aniso_shape_model_xld` creates the shape model from XLD contours, i.e., without the use of a template image.

The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_aniso_shape_model`. The center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with `set_shape_model_origin`. The model is generated for multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations and anisotropic scales (i.e., independent scales in the row and column direction) on each level. The model can be extended by clutter parameters with `set_shape_model_clutter`.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_aniso_shape_model_xld` returns with an error message.

If `NumLevels` is set to `'auto'`, `create_aniso_shape_model_xld` determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_aniso_shape_model_xld` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_aniso_shape_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_aniso_shape_model` may increase. In these cases, the number of pyramid levels should be selected manually.

AngleStart, AngleExtent, and AngleStep: The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the object can occur in the image. Note that the object can

only be found in this range of angles by `find_aniso_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_aniso_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_aniso_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_aniso_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value n such that `AngleStart` plus n times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax, ScaleRStep, and ScaleCStep: The parameters `ScaleRMin`, `ScaleRMax`, `ScaleCMin`, and `ScaleCMax` determine the range of possible anisotropic scales of the object in the row and column direction. A scale of 1 in both scale factors corresponds to the original size of the model. The parameters `ScaleRStep` and `ScaleCStep` determine the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in `find_aniso_shape_model`, these parameters specify the accuracy that is achievable for the scales in `find_aniso_shape_model`. Like `AngleStep`, `ScaleRStep` and `ScaleCStep` should be chosen based on the size of the object. If the respective range of scales is not an integer multiple of `ScaleRStep` and `ScaleCStep`, `ScaleRStep` and `ScaleCStep` are modified accordingly.

To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by `find_aniso_shape_model`, the range of possible scales is modified as follows: If there are no positive integer values n and m such that `ScaleRMin` plus n times `ScaleRStep` is exactly 1.0 and `ScaleCMin` plus m times `ScaleCStep` is exactly 1.0, `ScaleRMin` and `ScaleCMin` are decreased by up to `ScaleRStep` and `ScaleCStep`, respectively, and `ScaleRMax` and `ScaleCMax` are increased such that the range of possible scales is increased by `ScaleRStep` and `ScaleCStep`, respectively.

Note that the transformations are treated internally such that the scalings are applied first, followed by the rotation. Therefore, the model should usually be aligned such that it appears horizontally or vertically in the model image.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from 'none'. If `Optimization` = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_aniso_shape_model` to set the parameter `Greedy` to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to 'auto', `create_aniso_shape_model_xld` automatically determines the reduction of the number of model points.

Metric: The parameter `Metric` determines the conditions under which the model is recognized in the image.

If `Metric` = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric` = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_aniso_shape_model` will increase slightly in this case.

Note that the metrics ('use_polarity' and 'ignore_global_polarity') can only be selected if all `Contours` provide the attribute 'edge_direction', which defines the polarity of the edges. This attribute is available for contours created, e.g., with `edges_sub_pix` with the parameter `Method` set to, e.g., 'canny'. Otherwise, these two metrics can be selected with the operator `set_shape_model_metric`, which determines the polarity of the edges from an image.

If `Metric` = 'ignore_local_polarity', the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_aniso_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_aniso_shape_model_xld`, and to match them simultaneously with `find_aniso_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If `Metric = 'ignore_color_polarity'`, the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_aniso_shape_model` can also increase significantly. The metric `'ignore_color_polarity'` can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as `'ignore_local_polarity'`. It should be noted that for `Metric = 'ignore_color_polarity'` the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Note that the first two metrics (`'use_polarity'` and `'ignore_global_polarity'`) can only be selected if all `Contours` provide the attribute `'edge_direction'`, which defines the polarity of the edges. For more information about contour attributes like `'edge_direction'` see `get_contour_attrib_xld`. Otherwise, these two metrics can be selected with the operator `set_shape_model_metric`, which determines the polarity of the edges from an image.

MinContrast: With `MinContrast`, it can be determined which contrast the object edges must at least have in the recognition performed by `find_aniso_shape_model`. In other words, this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, `MinContrast` should be set to 10. If multichannel images are used for the model and the search images, and if the parameter `Metric` is set to `'ignore_color_polarity'` (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine `MinContrast`. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image `MinContrast` should be set to 17. If the model should be recognized in very low contrast images, `MinContrast` must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, `MinContrast` should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by `find_aniso_shape_model`.

Complete pregeneration of the model

Optionally, a second value can be passed in `Optimization`. This value determines whether the model is pre-generated completely or not. To do so, the second value of `Optimization` must be set to either `'pregeneration'` or `'no_pregeneration'`. If the second value is not used (i.e., if only one value is passed), the mode that is set with `set_system('pregenerate_shape_models', ...)` is used. With the default value (`'pregenerate_shape_models' = 'false'`), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, `find_aniso_shape_model` typically returns slightly lower scores, which may require setting a slightly lower value for `MinScore` than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if `AngleStep`, `ScaleRStep`, or `ScaleCStep` are too small or `AngleExtent` or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, `AngleStep`, `ScaleRStep`, or `ScaleCStep` must be enlarged or `AngleExtent` or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by `find_aniso_shape_model`, `AngleStep` $\geq 1^\circ$ and `ScaleRStep`, `ScaleCStep` ≥ 0.02 can be selected for models of a diameter smaller than about 200 pixels.

If `AngleStep = 'auto'` or `ScaleRStep`, `ScaleCStep = 'auto'` is selected, `create_aniso_shape_model_xld` automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using `get_shape_model_params`.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in

`find_aniso_shape_model`. Because of this, the recognition of the model might require slightly more time. Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

Attention

The XLD contours passed in `Contours` should have been scaled to approximately the average size of the object in the search images. This means that the products `ScaleRMin` × `ScaleRMax` and `ScaleCMin` × `ScaleCMax` should be approximately equal to 1.

Note that, in contrast to the operator `create_aniso_shape_model`, it is not possible to specify a minimum size of the model components. To avoid small model components in the shape model, short contours can be eliminated before calling `create_aniso_shape_model_xld` with the operator `select_contours_xld`.

Parameters

- ▷ **Contours** (input_object) xld_cont(-array) $\leadsto$ *object*
Input contours that will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ *integer / string*
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ *real*
Smallest rotation of the pattern.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ *real*
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in$ {6.29, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtent $\geq$ 0
- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ *real / string*
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep $\geq$ 0 && AngleStep $\leq$ pi / 2
- ▷ **ScaleRMin** (input_control) number $\leadsto$ *real*
Minimum scale of the pattern in the row direction.
Default: 0.9
Suggested values: ScaleRMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleRMin $>$ 0
- ▷ **ScaleRMax** (input_control) number $\leadsto$ *real*
Maximum scale of the pattern in the row direction.
Default: 1.1
Suggested values: ScaleRMax $\in$ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
Restriction: ScaleRMax $\geq$ ScaleRMin
- ▷ **ScaleRStep** (input_control) number $\leadsto$ *real / string*
Scale step length (resolution) in the row direction.
Default: 'auto'
Suggested values: ScaleRStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleRStep $\geq$ 0
- ▷ **ScaleCMin** (input_control) number $\leadsto$ *real*
Minimum scale of the pattern in the column direction.
Default: 0.9
Suggested values: ScaleCMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleCMin $>$ 0
- ▷ **ScaleCMax** (input_control) number $\leadsto$ *real*
Maximum scale of the pattern in the column direction.
Default: 1.1
Suggested values: ScaleCMax $\in$ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
Restriction: ScaleCMax $\geq$ ScaleCMin

- ▷ **ScaleCStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution) in the column direction.
Default: 'auto'
Suggested values: ScaleCStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleCStep $\geq$ 0
- ▷ **Optimization** (input_control) string(-array) $\leadsto$ string
Kind of optimization and optionally method used for generating the model.
Default: 'auto'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high', 'pregeneration', 'no_pregeneration'}
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'ignore_local_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer
Minimum contrast of the objects in the search images.
Default: 5
Suggested values: MinContrast $\in$ {1, 2, 3, 5, 7, 10, 20, 30, 40}
- ▷ **ModelID** (output_control) shape_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_aniso_shape_model_xld` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameter `NumLevels` is chosen such that the model contains too few points, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`read_contour_xld_dxf`, `edges_sub_pix`, `select_contours_xld`

Possible Successors

`find_aniso_shape_model`, `find_aniso_shape_models`, `get_shape_model_params`,
`clear_shape_model`, `write_shape_model`, `set_shape_model_origin`,
`set_shape_model_param`, `set_shape_model_metric`, `set_shape_model_clutter`

Alternatives

`create_generic_shape_model`

`set_system`, `get_system`

Module

Matching

create_generic_shape_model (: : : ModelID)

Create a shape model.

The operator `create_generic_shape_model` creates a shape model and returns its handle in `ModelID`.

The created model is not trained. See `train_generic_shape_model` for information about training a model.

Parameters

- ▷ **ModelID** (output_control) shape_model $\leadsto$ handle
Handle of the shape model.

Result

If successful the operator `create_generic_shape_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`set_generic_shape_model_param`, `train_generic_shape_model`, `write_shape_model`,
`set_shape_model_origin`

Module

Matching

```
create_scaled_shape_model ( Template : : NumLevels, AngleStart,
    AngleExtent, AngleStep, ScaleMin, ScaleMax, ScaleStep,
    Optimization, Metric, Contrast, MinContrast : ModelID )
```

Prepare an isotropically scaled shape model for matching.

The operator `create_scaled_shape_model` prepares a template, which is passed in the image `Template`, as an isotropically scaled shape model used for matching. The ROI of the model is passed as the domain of `Template`.

The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_scaled_shape_model`. The center of gravity of the domain (region) of the model image `Template` is used as the origin (reference point) of the model. A different origin can be set with `set_shape_model_origin`. The model is generated using multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations and scales on each level. The model can be extended by clutter parameters with `set_shape_model_clutter`.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. This can be checked using the output of `inspect_shape_model`. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_scaled_shape_model` returns with an error message.

If `NumLevels` is set to 'auto' (or 0 for backwards compatibility), `create_scaled_shape_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_scaled_shape_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_scaled_shape_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_scaled_shape_model` may increase. In these cases, the number of pyramid levels should be selected using the output of `inspect_shape_model`.

AngleStart, AngleExtent and AngleStep: The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by `find_scaled_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_scaled_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_scaled_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_scaled_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value n such that `AngleStart` plus n times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

ScaleMin, ScaleMax, and ScaleStep: The parameters `ScaleMin` and `ScaleMax` determine the range of possible scales (sizes) of the model. A scale of 1 corresponds to the original size of the model. The parameter `ScaleStep` determines the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in `find_scaled_shape_model`, this parameter specifies the accuracy that is achievable for the scales in `find_scaled_shape_model`. Like `AngleStep`, `ScaleStep` should be chosen based on the size of the object. If the range of scales is not an integer multiple of `ScaleStep`, `ScaleStep` is modified accordingly. To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by `find_scaled_shape_model`, the range of possible scales is modified as follows: If there is no positive integer value n such that `ScaleMin` plus n times `ScaleStep` is exactly 1.0, `ScaleMin` is decreased by up to `ScaleStep` and `ScaleMax` is increased such that the range of possible scales is increased by `ScaleStep`.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from 'none'. If `Optimization` = 'none', all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_scaled_shape_model` to set the parameter `Greediness` to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to 'auto', `create_scaled_shape_model` automatically determines the reduction of the number of model points.

Metric: The parameter `Metric` determines the conditions under which the model is recognized in the image.

If `Metric` = 'use_polarity', the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric` = 'ignore_global_polarity', the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_scaled_shape_model` will increase slightly in this case.

If `Metric` = 'ignore_local_polarity', the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_scaled_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_scaled_shape_model`, and to match them simultaneously with `find_scaled_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If `Metric` = 'ignore_color_polarity', the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_scaled_shape_model` can also increase significantly. The metric 'ignore_color_polarity' can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as 'ignore_local_polarity'. It should be noted that for `Metric` = 'ignore_color_polarity' the number of channels in the model creation with `create_scaled_shape_model` and in the search with `find_scaled_shape_model` can be different. This can, for example, be used to create a model from a synthetically generated single-channel image. Furthermore, it should be noted that the channels do not need

to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Contrast: The parameter `Contrast` determines the contrast the model points must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. `Contrast` should be chosen such that only the significant features of the template are used for the model. `Contrast` can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see `hysteresis_threshold`. Optionally, `Contrast` can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in `Contrast`. In this case, the first two values can simply be set to identical values. The effect of this parameter can be checked in advance with `inspect_shape_model`.

If `Contrast` is set to `'auto'`, `create_scaled_shape_model` determines the three above described values automatically. Besides, only the contrast (`'auto_contrast'`), the hysteresis thresholds (`'auto_contrast_hyst'`), or the minimum size (`'auto_min_size'`) can be determined automatically. The remaining values that are not determined automatically can additionally be passed in the form of a tuple. Also various combinations are allowed: If, for example, [`'auto_contrast'`, `'auto_min_size'`] is passed, both the contrast and the minimum size are determined automatically. If [`'auto_min_size'`, 20, 30] is passed, the minimum size is determined automatically while the hysteresis thresholds are set to 20 and 30, etc. In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with `determine_shape_model_params` and subsequently verified using `inspect_shape_model` before calling `create_scaled_shape_model`. Note that `MinContrast` influences the automatic contrast estimation, and hence also the estimation of the minimum size.

MinContrast: With `MinContrast`, it can be determined which contrast the model must at least have in the recognition performed by `find_scaled_shape_model`. In other words, this parameter separates the model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, `MinContrast` should be set to 10. If multichannel images are used for the model and the search images, and if the parameter `Metric` is set to `'ignore_color_polarity'` (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine `MinContrast`. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image `MinContrast` should be set to 17. Obviously, `MinContrast` must be smaller than `Contrast`. If the model should be recognized in very low contrast images, `MinContrast` must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, `MinContrast` should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by `find_scaled_shape_model`.

If `MinContrast` is set to `'auto'`, the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using `get_shape_model_params`.

Complete pregeneration of the model

Optionally, a second value can be passed in `Optimization`. This value determines whether the model is pre-generated completely or not. To do so, the second value of `Optimization` must be set to either `'pregeneration'` or `'no_pregeneration'`. If the second value is not used (i.e., if only one value is passed), the mode that is set with `set_system('pregenerate_shape_models', ...)` is used. With the default value (`'pregenerate_shape_models' = 'false'`), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should

also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, `find_scaled_shape_model` typically returns slightly lower scores, which may require setting a slightly lower value for `MinScore` than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if `AngleStep` or `ScaleStep` are too small or `AngleExtent` or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either `AngleStep` or `ScaleStep` must be enlarged or `AngleExtent` or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by `find_scaled_shape_model`, `AngleStep` $\geq 1^\circ$ and `ScaleStep` ≥ 0.02 can be selected for models of a diameter smaller than about 200 pixels.

If `AngleStep` = 'auto' or `ScaleStep` = 'auto' (or 0 for backwards compatibility in both cases) is selected, `create_scaled_shape_model` automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using `get_shape_model_params`.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in `find_scaled_shape_model`. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

Parameters

- ▷ **Template** (input_object) (multichannel-)image $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the pattern.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in$ {6.29, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtent ≥ 0
- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ real / string
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep ≥ 0 && AngleStep $\leq \pi / 2$
- ▷ **ScaleMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern.
Default: 0.9
Suggested values: ScaleMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleMin > 0
- ▷ **ScaleMax** (input_control) number $\leadsto$ real
Maximum scale of the pattern.
Default: 1.1
Suggested values: ScaleMax $\in$ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
Restriction: ScaleMax $\geq$ ScaleMin

- ▷ **ScaleStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution).
Default: 'auto'
Suggested values: ScaleStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleStep $\geq$ 0
- ▷ **Optimization** (input_control) string(-array) $\leadsto$ string
Kind of optimization and optionally method used for generating the model.
Default: 'auto'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high', 'pregeneration', 'no_pregeneration'}
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **Contrast** (input_control) number(-array) $\leadsto$ integer / string
Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
Default: 'auto'
Suggested values: Contrast $\in$ {'auto', 'auto_contrast', 'auto_contrast_hyst', 'auto_min_size', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer / string
Minimum contrast of the objects in the search images.
Default: 'auto'
Suggested values: MinContrast $\in$ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}
Restriction: MinContrast $<$ Contrast
- ▷ **ModelID** (output_control) shape_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_scaled_shape_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameters `NumLevels` and `Contrast` are chosen such that the model contains too few points, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

Module

Matching

```
create_scaled_shape_model_xld ( Contours : : NumLevels,
    AngleStart, AngleExtent, AngleStep, ScaleMin, ScaleMax,
    ScaleStep, Optimization, Metric, MinContrast : ModelID )
```

Prepare an isotropically scaled shape model for matching from XLD contours.

The operator `create_scaled_shape_model_xld` creates an isotropically scaled shape model used for matching from the XLD contours passed in `Contours`. The XLD contours represent the gray value edges of the object to be searched for. In contrast to the operator `create_scaled_shape_model`, which creates a shape model from a template image, the operator `create_scaled_shape_model_xld` creates the shape model from XLD contours, i.e., without the use of a template image.

The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_scaled_shape_model`. The center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with `set_shape_model_origin`. The model is generated for multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations and scales on each level. The model can be extended by clutter parameters with `set_shape_model_clutter`.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_scaled_shape_model_xld` returns with an error message. If `NumLevels` is set to 'auto', `create_scaled_shape_model_xld` determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_scaled_shape_model_xld` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_scaled_shape_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_scaled_shape_model` may increase. In these cases, the number of pyramid levels should be selected manually.

AngleStart, AngleExtent, and AngleStep: The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the object can occur in the image during the search. Note that the object can only be found in this range of angles by `find_scaled_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_scaled_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_scaled_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_scaled_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value n such that `AngleStart` plus n times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

ScaleMin, ScaleMax, and ScaleStep: The parameters `ScaleMin` and `ScaleMax` determine the range of possible scales (sizes) of the object. A scale of 1 corresponds to the original size of the model. The parameter `ScaleStep` determines the step length within the selected range of scales. Hence, if subpixel accuracy is not specified in `find_scaled_shape_model`, this parameter specifies the accuracy that is achievable for the scales in `find_scaled_shape_model`. Like `AngleStep`, `ScaleStep` should be chosen based on the size of the object. If the range of scales is not an integer multiple of `ScaleStep`, `ScaleStep` is modified accordingly. To ensure that for model instances that are not scaled scale values of exactly 1.0 are returned by `find_scaled_shape_model`, the range of possible scales is modified as follows: If there is no positive integer value n such that `ScaleMin` plus n times `ScaleStep` is exactly 1.0, `ScaleMin` is decreased by up to `ScaleStep` and `ScaleMax` is increased such that the range of possible scales is increased by `ScaleStep`.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from `'none'`. If `Optimization = 'none'`, all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_scaled_shape_model` to set the parameter `Greediness` to a smaller value, e.g., `0.7` or `0.8`. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to `'auto'`, `create_scaled_shape_model_xld` automatically determines the reduction of the number of model points.

Metric: The parameter `Metric` determines the conditions under which the model is recognized in the image.

If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_scaled_shape_model` will increase slightly in this case.

Note that the metrics (`'use_polarity'` and `'ignore_global_polarity'`) can only be selected if all `Contours` provide the attribute `'edge_direction'`, which defines the polarity of the edges. This attribute is available for contours created, e.g., with `edges_sub_pix` with the parameter `Method` set to, e.g., `'canny'`. Otherwise, these two metrics can be selected with the operator `set_shape_model_metric`, which determines the polarity of the edges from an image.

If `Metric = 'ignore_local_polarity'`, the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_scaled_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_scaled_shape_model_xld`, and to match them simultaneously with `find_scaled_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If `Metric = 'ignore_color_polarity'`, the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_scaled_shape_model` can also increase significantly. The metric `'ignore_color_polarity'` can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as `'ignore_local_polarity'`. It should be noted that for `Metric = 'ignore_color_polarity'` the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Note that the first two metrics (`'use_polarity'` and `'ignore_global_polarity'`) can only be selected if all `Contours` provide the attribute `'edge_direction'`, which defines the polarity of the edges. For more information about contour attributes like `'edge_direction'` see `get_contour_attrib_xld`. Otherwise, these two metrics can be selected with the operator `set_shape_model_metric`, which determines the polarity of the edges from an image.

MinContrast: With `MinContrast`, it can be determined which contrast the object edges must at least have in the recognition performed by `find_scaled_shape_model`. In other words, this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, `MinContrast` should be set to 10. If multichannel images are used for the model and the search images, and if the parameter `Metric` is set to `'ignore_color_polarity'` (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine `MinContrast`. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image `MinContrast` should be set to 17. If the model should be recognized in very low contrast images, `MinContrast` must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, `MinContrast` should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by `find_scaled_shape_model`.

Complete pregeneration of the model

Optionally, a second value can be passed in `Optimization`. This value determines whether the model is pre-generated completely or not. To do so, the second value of `Optimization` must be set to either `'pregeneration'` or `'no_pregeneration'`. If the second value is not used (i.e., if only one value is passed), the mode that is set with `set_system('pregenerate_shape_models', ...)` is used. With the default value (`'pregenerate_shape_models' = 'false'`), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, `find_scaled_shape_model` typically returns slightly lower scores, which may require setting a slightly lower value for `MinScore` than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle and scale range and stored in memory. The memory required to store the model is proportional to the number of angle steps, the number of scale steps, and the number of points in the model. Hence, if `AngleStep` or `ScaleStep` are too small or `AngleExtent` or the range of scales are too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either `AngleStep` or `ScaleStep` must be enlarged or `AngleExtent` or the range of scales must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by `find_scaled_shape_model`, `AngleStep` $\geq 1^\circ$ and `ScaleStep` ≥ 0.02 can be selected for models of a diameter smaller than about 200 pixels.

If `AngleStep = 'auto'` or `ScaleStep = 'auto'` is selected, `create_scaled_shape_model_xld` automatically determines a suitable angle or scale step length, respectively, based on the size of the model. The automatically computed angle and scale step lengths can be queried using `get_shape_model_params`.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in `find_scaled_shape_model`. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

Attention

The XLD contours passed in `Contours` should have been scaled to approximately the average size of the object in the search images. This means that the product `ScaleMin` $\times$ `ScaleMax` should be approximately equal to 1.

Note that, in contrast to the operator `create_scaled_shape_model`, it is not possible to specify a minimum size of the model components. To avoid small model components in the shape model, short contours can be eliminated before calling `create_scaled_shape_model_xld` with the operator `select_contours_xld`.

Parameters

- ▷ **Contours** (input_object) xld_cont(-array) $\leadsto$ object
Input contours that will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the pattern.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in$ {6.29, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtent ≥ 0

- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ real / string
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep ≥ 0 && AngleStep $\leq \pi / 2$
- ▷ **ScaleMin** (input_control) number $\leadsto$ real
Minimum scale of the pattern.
Default: 0.9
Suggested values: ScaleMin $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: ScaleMin > 0
- ▷ **ScaleMax** (input_control) number $\leadsto$ real
Maximum scale of the pattern.
Default: 1.1
Suggested values: ScaleMax $\in$ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
Restriction: ScaleMax $\geq$ ScaleMin
- ▷ **ScaleStep** (input_control) number $\leadsto$ real / string
Scale step length (resolution).
Default: 'auto'
Suggested values: ScaleStep $\in$ {'auto', 0.01, 0.02, 0.05, 0.1, 0.15, 0.2}
Restriction: ScaleStep ≥ 0
- ▷ **Optimization** (input_control) string(-array) $\leadsto$ string
Kind of optimization and optionally method used for generating the model.
Default: 'auto'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high', 'pregeneration', 'no_pregeneration'}
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'ignore_local_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer
Minimum contrast of the objects in the search images.
Default: 5
Suggested values: MinContrast $\in$ {1, 2, 3, 5, 7, 10, 20, 30, 40}
- ▷ **ModelID** (output_control) shape_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_scaled_shape_model_xld` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameter `NumLevels` is chosen such that the model contains too few points, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

```
create_shape_model ( Template : : NumLevels, AngleStart,
                   AngleExtent, AngleStep, Optimization, Metric, Contrast,
                   MinContrast : ModelID )
```

Prepare a shape model for matching.

The operator `create_shape_model` prepares a template, which is passed in the image `Template`, as a shape model used for matching. The ROI of the model is passed as the domain of `Template`.

The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_shape_model`. The center of gravity of the domain (region) of the model image `Template` is used as the origin (reference point) of the model. A different origin can be set with `set_shape_model_origin`. The model is generated using multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations on each level. The model can be extended by clutter parameters with `set_shape_model_clutter`.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. This can be checked using the output of `inspect_shape_model`. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_shape_model` returns with an error message.

If `NumLevels` is set to `'auto'` (or 0 for backwards compatibility), `create_shape_model` determines the number of pyramid levels automatically. The automatically computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_shape_model` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_shape_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_shape_model` may increase. In these cases, the number of pyramid levels should be selected using the output of `inspect_shape_model`.

AngleStart, AngleExtent, and AngleStep: The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the model can occur in the image. Note that the model can only be found in this range of angles by `find_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not possess many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly. To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value `n` such that `AngleStart` plus `n` times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from `'none'`. If `Optimization` = `'none'`, all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_shape_model` to set the parameter `Greediness` to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to `'auto'`, `create_shape_model` automatically determines the reduction of the number of model points.

Metric: The parameter `Metric` determines the conditions under which the model is recognized in the image.

If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_shape_model` will increase slightly in this case.

If `Metric = 'ignore_local_polarity'`, the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_shape_model`, and to match them simultaneously with `find_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If `Metric = 'ignore_color_polarity'`, the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_shape_model` can also increase significantly. The metric `'ignore_color_polarity'` can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as `'ignore_local_polarity'`. It should be noted that for `Metric = 'ignore_color_polarity'` the number of channels in the model creation with `create_shape_model` and in the search with `find_shape_model` can be different. This can, for example, be used to create a model from a synthetically generated single-channel image. Furthermore, it should be noted that the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Contrast: The parameter `Contrast` determines the contrast the model points must have. The contrast is a measure for local gray value differences between the object and the background and between different parts of the object. `Contrast` should be chosen such that only the significant features of the template are used for the model. `Contrast` can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see `hysteresis_threshold`. Optionally, `Contrast` can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in `Contrast`. In this case, the first two values can simply be set to identical values. The effect of this parameter can be checked in advance with `inspect_shape_model`.

If `Contrast` is set to `'auto'`, `create_shape_model` determines the three above described values automatically. Only the contrast (`'auto_contrast'`), the hysteresis thresholds (`'auto_contrast_hyst'`), or the minimum size (`'auto_min_size'`) can be determined automatically. The remaining values that are not determined automatically can additionally be passed in the form of a tuple. Also various combinations are allowed: If, for example, `['auto_contrast','auto_min_size']` is passed, both the contrast and the minimum size are determined automatically. If `['auto_min_size',20,30]` is passed, the minimum size is determined automatically while the hysteresis thresholds are set to 20 and 30, etc. In certain cases, it might happen that the automatic determination of the contrast thresholds is not satisfying. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed because of application-specific reasons or if the object contains several different contrasts. Therefore, the contrast thresholds should be automatically determined with `determine_shape_model_params` and subsequently verified using `inspect_shape_model` before calling `create_shape_model`. Note that `MinContrast` influences the automatic contrast estimation, and hence also the estimation of the minimum size.

MinContrast: With `MinContrast`, it can be determined which contrast the model must at least have in the recognition performed by `find_shape_model`. In other words, this parameter separates the model from

the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, `MinContrast` should be set to 10. If multichannel images are used for the model and the search images, and if the parameter `Metric` is set to `'ignore_color_polarity'` (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine `MinContrast`. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image `MinContrast` should be set to 17. Obviously, `MinContrast` must be smaller than `Contrast`. If the model should be recognized in very low contrast images, `MinContrast` must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, `MinContrast` should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by `find_shape_model`.

If `MinContrast` is set to `'auto'`, the minimum contrast is determined automatically based on the noise in the model image. Consequently, an automatic determination only makes sense if the image noise during the recognition is similar to the noise in the model image. Furthermore, in some cases it is advisable to increase the automatically determined value in order to increase the robustness against occlusions (see above). The automatically computed minimum contrast can be queried using `get_shape_model_params`.

Complete pregeneration of the model

Optionally, a second value can be passed in `Optimization`. This value determines whether the model is pre-generated completely or not. To do so, the second value of `Optimization` must be set to either `'pregeneration'` or `'no_pregeneration'`. If the second value is not used (i.e., if only one value is passed), the mode that is set with `set_system('pregenerate_shape_models', ...)` is used. With the default value (`'pregenerate_shape_models' = 'false'`), the model is not pregenerated completely. The complete pregeneration of the model normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, `find_shape_model` typically returns slightly lower scores, which may require setting a slightly lower value for `MinScore` than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle range and stored in memory. The memory required to store the model is proportional to the number of angle steps and the number of points in the model. Hence, if `AngleStep` is too small or `AngleExtent` too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either `AngleStep` must be enlarged or `AngleExtent` must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by `find_shape_model`, `AngleStep` ≥ 1 can be selected for models of a diameter smaller than about 200 pixels.

If `AngleStep = 'auto'` (or 0 for backwards compatibility) is selected, `create_shape_model` automatically determines a suitable angle step length based on the size of the model. The automatically computed angle step length can be queried using `get_shape_model_params`.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in `find_shape_model`. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

Parameters

- ▷ **Template** (input_object) (multichannel-)image $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the pattern.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39\}$
Restriction: AngleExtent ≥ 0
- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ real / string
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in \{'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873\}$
Restriction: AngleStep ≥ 0 && AngleStep $\leq \pi / 2$
- ▷ **Optimization** (input_control) string(-array) $\leadsto$ string
Kind of optimization and optionally method used for generating the model.
Default: 'auto'
List of values: Optimization $\in \{'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high', 'pregeneration', 'no_pregeneration'\}$
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: Metric $\in \{'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'\}$
- ▷ **Contrast** (input_control) number(-array) $\leadsto$ integer / string
Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
Default: 'auto'
Suggested values: Contrast $\in \{'auto', 'auto_contrast', 'auto_contrast_hyst', 'auto_min_size', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160\}$
- ▷ **MinContrast** (input_control) number $\leadsto$ integer / string
Minimum contrast of the objects in the search images.
Default: 'auto'
Suggested values: MinContrast $\in \{'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40\}$
Restriction: MinContrast $<$ Contrast
- ▷ **ModelID** (output_control) shape_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_shape_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameters `NumLevels` and `Contrast` are chosen such that the model contains too few points, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`draw_region`, `reduce_domain`, `threshold`

Possible Successors

`find_shape_model`, `find_shape_models`, `get_shape_model_params`, `clear_shape_model`, `write_shape_model`, `set_shape_model_origin`, `set_shape_model_clutter`

Alternatives

`create_generic_shape_model`

Module

Matching

```
create_shape_model_xld ( Contours : : NumLevels, AngleStart,
    AngleExtent, AngleStep, Optimization, Metric,
    MinContrast : ModelID )
```

Prepare a shape model for matching from XLD contours.

The operator `create_shape_model_xld` creates a shape model used for matching from the XLD contours passed in `Contours`. The XLD contours represent the gray value edges of the object to be searched for. In contrast to the operator `create_shape_model`, which creates a shape model from a template image, the operator `create_shape_model_xld` creates the shape model from XLD contours, i.e., without the use of a template image.

The output parameter `ModelID` is a handle for this model, which is used in subsequent calls to `find_shape_model`. The center of gravity of the smallest surrounding rectangle of the `Contours` that is parallel to the coordinate axes is used as the origin (reference point) of the model. A different origin can be set with `set_shape_model_origin`. The model is generated for multiple image pyramid levels and is stored in memory. If a complete pregeneration of the model is selected (see below), the model is generated at multiple rotations on each level. The model can be extended by clutter parameters with `set_shape_model_clutter`.

Input parameters in detail

NumLevels: The number of pyramid levels is determined with the parameter `NumLevels`. It should be chosen as large as possible because by this the time necessary to find the object is significantly reduced. On the other hand, `NumLevels` must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. If not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, `create_shape_model_xld` returns with an error message.

If `NumLevels` is set to `'auto'`, `create_shape_model_xld` determines the number of pyramid levels automatically. The computed number of pyramid levels can be queried using `get_shape_model_params`. In rare cases, it might happen that `create_shape_model_xld` determines a value for the number of pyramid levels that is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_shape_model` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_shape_model` may increase. In these cases, the number of pyramid levels should be selected manually.

AngleStart, AngleExtent, and AngleStep: The parameters `AngleStart` and `AngleExtent` determine the range of possible rotations, in which the object can occur in the image during the search. Note that the object can only be found in this range of angles by `find_shape_model`. The parameter `AngleStep` determines the step length within the selected range of angles. Hence, if subpixel accuracy is not specified in `find_shape_model`, this parameter specifies the accuracy that is achievable for the angles in `find_shape_model`. `AngleStep` should be chosen based on the size of the object. Smaller models do not possess many different discrete rotations in the image, and hence `AngleStep` should be chosen larger for smaller models. If `AngleExtent` is not an integer multiple of `AngleStep`, `AngleStep` is modified accordingly.

To ensure that for model instances without rotation angle values of exactly 0.0 are returned by `find_shape_model`, the range of possible rotations is modified as follows: If there is no positive integer value `n` such that `AngleStart` plus `n` times `AngleStep` is exactly 0.0, `AngleStart` is decreased by up to `AngleStep` and `AngleExtent` is increased by `AngleStep`.

Optimization: For particularly large models, it may be useful to reduce the number of model points by setting `Optimization` to a value different from `'none'`. If `Optimization` = `'none'`, all model points are stored. In all other cases, the number of points is reduced according to the value of `Optimization`. If the number of points is reduced, it may be necessary in `find_shape_model` to set the parameter `Greediness` to a smaller value, e.g., 0.7 or 0.8. For small models, the reduction of the number of model points does not result

in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined.

If `Optimization` is set to `'auto'`, `create_shape_model_xld` automatically determines the reduction of the number of model points.

Metric: The parameter `Metric` determines the conditions under which the model is recognized in the image.

If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background.

If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_shape_model` will increase slightly in this case.

Note that the metrics (`'use_polarity'` and `'ignore_global_polarity'`) can only be selected if all `Contours` provide the attribute `'edge_direction'`, which defines the polarity of the edges. This attribute is available for contours created, e.g., with `edges_sub_pix` with the parameter `Method` set to, e.g., `'canny'`. Otherwise, these two metrics can be selected with the operator `set_shape_model_metric`, which determines the polarity of the edges from an image.

If `Metric = 'ignore_local_polarity'`, the model is found even if the contrast changes locally. This mode can, for example, be useful if the object consists of a part with medium gray value, within which either darker or brighter sub-objects lie. Since in this case the runtime of `find_shape_model` increases significantly, it is usually better to create several models that reflect the possible contrast variations of the object with `create_shape_model_xld`, and to match them simultaneously with `find_shape_models`.

The above three metrics can only be applied to single-channel images. If a multichannel image is used as the model image or as the search image, only the first channel will be used (and no error message will be returned).

If `Metric = 'ignore_color_polarity'`, the model is found even if the color contrast changes locally. This is, for example, the case if parts of the object can change their color, e.g., from red to green. In particular, this mode is useful if it is not known in advance in which channels the object is visible. In this mode, the runtime of `find_shape_model` can also increase significantly. The metric `'ignore_color_polarity'` can be used for images with an arbitrary number of channels. If it is used for single-channel images it has the same effect as `'ignore_local_polarity'`. It should be noted that for `Metric = 'ignore_color_polarity'` the channels do not need to contain a spectral subdivision of the light (like in an RGB image). The channels can, for example, also contain images of the same object that were obtained by illuminating the object from different directions.

Note that the first two metrics (`'use_polarity'` and `'ignore_global_polarity'`) can only be selected if all `Contours` provide the attribute `'edge_direction'`, which defines the polarity of the edges. For more information about contour attributes like `'edge_direction'` see `get_contour_attrib_xld`. Otherwise, these two metrics can be selected with the operator `set_shape_model_metric`, which determines the polarity of the edges from an image.

MinContrast: With `MinContrast`, it can be determined which contrast the object edges must at least have in the recognition performed by `find_shape_model`. In other words, this parameter separates the object from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, `MinContrast` should be set to 10. If multichannel images are used for the model and the search images, and if the parameter `Metric` is set to `'ignore_color_polarity'` (see above) the noise in one channel must be multiplied by the square root of the number of channels to determine `MinContrast`. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image `MinContrast` should be set to 17. If the model should be recognized in very low contrast images, `MinContrast` must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, `MinContrast` should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the position and rotation of the model are extracted robustly and accurately by `find_shape_model`.

Complete pregeneration of the model

Optionally, a second value can be passed in `Optimization`. This value determines whether the model is pre-generated completely or not. To do so, the second value of `Optimization` must be set to either `'pregeneration'` or `'no_pregeneration'`. If the second value is not used (i.e., if only one value is passed), the mode that is set with `set_system('pregenerate_shape_models', ...)` is used. With the default value (`'pregenerate_shape_models' = 'false'`), the model is not pregenerated completely. The complete pregeneration of the model

normally leads to slightly lower runtimes because the model does not need to be transformed at runtime. However, in this case, the memory requirements and the time required to create the model are significantly higher. It should also be noted that it cannot be expected that the two modes return exactly identical results because transforming the model at runtime necessarily leads to different internal data for the transformed models than pregenerating the transformed models. For example, if the model is not pregenerated completely, `find_shape_model` typically returns slightly lower scores, which may require setting a slightly lower value for `MinScore` than for a completely pregenerated model. Furthermore, the poses obtained by interpolation may differ slightly in the two modes. If maximum accuracy is desired, the pose of the model should be determined by least-squares adjustment.

If a complete pregeneration of the model is selected, the model is pregenerated for the selected angle range and stored in memory. The memory required to store the model is proportional to the number of angle steps and the number of points in the model. Hence, if `AngleStep` is too small or `AngleExtent` too big, it may happen that the model no longer fits into the (virtual) memory. In this case, either `AngleStep` must be enlarged or `AngleExtent` must be reduced. In any case, it is desirable that the model completely fits into the main memory, because this avoids paging by the operating system, and hence the time to find the object will be much smaller. Since angles can be determined with subpixel resolution by `find_shape_model`, `AngleStep` ≥ 1 can be selected for models of a diameter smaller than about 200 pixels.

If `AngleStep` = 'auto' is selected, `create_shape_model_xld` automatically determines a suitable angle step length based on the size of the model. The automatically computed angle step length can be queried using `get_shape_model_params`.

If a complete pregeneration of the model is not selected, the model is only created in a reference pose on each pyramid level. In this case, the model must be transformed to the different angles and scales at runtime in `find_shape_model`. Because of this, the recognition of the model might require slightly more time.

Note that pregenerated shape models are tailored to a specific image size. For runtime reasons using images of different sizes during the search with the same model in parallel is not supported. In this case, copies of the same model must be used, otherwise the program may crash!

Attention

Note that, in contrast to the operator `create_shape_model`, it is not possible to specify a minimum size of the model components. To avoid small model components in the shape model, short contours can be eliminated before calling `create_shape_model_xld` with the operator `select_contours_xld`.

Parameters

- ▷ **Contours** (input_object) xld_cont(-array) $\leadsto$ *object*
Input contours that will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ *integer / string*
Maximum number of pyramid levels.
Default: 'auto'
List of values: NumLevels $\in$ {'auto', 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ *real*
Smallest rotation of the pattern.
Default: -0.39
Suggested values: AngleStart $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ *real*
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in$ {6.29, 3.14, 1.57, 0.79, 0.39}
Restriction: AngleExtent ≥ 0
- ▷ **AngleStep** (input_control) angle.rad $\leadsto$ *real / string*
Step length of the angles (resolution).
Default: 'auto'
Suggested values: AngleStep $\in$ {'auto', 0.0175, 0.0349, 0.0524, 0.0698, 0.0873}
Restriction: AngleStep ≥ 0 && AngleStep $\leq \pi / 2$
- ▷ **Optimization** (input_control) string(-array) $\leadsto$ *string*
Kind of optimization and optionally method used for generating the model.
Default: 'auto'
List of values: Optimization $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high', 'pregeneration', 'no_pregeneration'}

- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'ignore_local_polarity'
List of values: Metric $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}
- ▷ **MinContrast** (input_control) number $\leadsto$ integer
Minimum contrast of the objects in the search images.
Default: 5
Suggested values: MinContrast $\in$ {1, 2, 3, 5, 7, 10, 20, 30, 40}
- ▷ **ModelID** (output_control) shape_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `create_shape_model_xld` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameter `NumLevels` is chosen such that the model contains too few points, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Matching

deserialize_shape_model (: : SerializedItemHandle : ModelID)

Deserialize a serialized shape model.

`deserialize_shape_model` deserializes a shape model, that was serialized by `serialize_shape_model` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized shape model is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created shape model with the handle `ModelID`.

Parameters

- ▷ **SerializedItemHandle** (input_control) serialized_item $\leadsto$ handle
Handle of the serialized item.
- ▷ **ModelID** (output_control) shape_model $\leadsto$ handle
Handle of the model.

Result

If the parameters are valid, the operator `deserialize_shape_model` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Module

Matching

```
determine_shape_model_params ( Template : : NumLevels,
    AngleStart, AngleExtent, ScaleMin, ScaleMax, Optimization,
    Metric, Contrast, MinContrast, Parameters : ParameterName,
    ParameterValue )
```

Determine the parameters of a shape model.

`determine_shape_model_params` determines certain parameters of a shape model automatically from the model image [Template](#). The parameters to be determined can be specified with [Parameters](#). `determine_shape_model_params` can be used to determine the same parameters that are determined automatically when the respective parameter in [create_shape_model](#), [create_scaled_shape_model](#), or [create_aniso_shape_model](#) is set to 'auto': the number of pyramid levels ([Parameters](#) = 'num_levels'), the angle step length ([Parameters](#) = 'angle_step'), the scale step length ([Parameters](#) = 'scale_step' for isotropic scaling and 'scale_r_step' and/or 'scale_c_step' for anisotropic scaling), the kind of optimization ([Parameters](#) = 'optimization'), the threshold ([Parameters](#) = 'contrast') or the hysteresis thresholds ([Parameters](#) = 'contrast_hyst') for the contrast, the minimum size of the object parts ([Parameters](#) = 'min_size'), and the minimum contrast ([Parameters](#) = 'min_contrast'). By passing a tuple of the above values in [Parameters](#), an arbitrary combination of these parameters can be determined. If all of the above parameters should be determined, the value 'all' can be passed. In this case both hysteresis thresholds are determined, i.e., the operator behaves like passing 'contrast_hyst' instead of 'contrast'.

`determine_shape_model_params` is mainly useful to determine the above parameters before creating the model, e.g., in an interactive system, which makes suggestions for these parameters to the user, but enables the user to modify the suggested values.

The automatically determined parameters are returned as a name-value pair in [ParameterName](#) and [ParameterValue](#). The parameter names in [ParameterName](#) are identical to the names in [Parameters](#), where, of course, the value 'all' is replaced by the actual parameter names. An exception is the parameter 'contrast_hyst', for which the two values 'contrast_low' and 'contrast_high' are returned.

The remaining parameters ([NumLevels](#), [AngleStart](#), [AngleExtent](#), [ScaleMin](#), [ScaleMax](#), [Optimization](#), [Metric](#), [Contrast](#), and [MinContrast](#)) have the same meaning as in [create_shape_model](#), [create_scaled_shape_model](#), and [create_aniso_shape_model](#). The description of these parameters can be looked up with these operators. These parameters are used by `determine_shape_model_params` to calculate the parameters to be determined in the same manner as in [create_shape_model](#), [create_scaled_shape_model](#), and [create_aniso_shape_model](#). It should be noted that if the parameters of a shape model with isotropic scaling should be determined, i.e., if [Parameters](#) contains 'scale_step' either explicitly or implicitly via 'all', the parameters [ScaleMin](#) and [ScaleMax](#) must contain one value each. If the parameters of a shape model with anisotropic scaling should be determined, i.e., if [Parameters](#) contains 'scale_r_step' or 'scale_c_step' either explicitly or implicitly, the parameters [ScaleMin](#) and [ScaleMax](#) must contain two values each. In this case, the first value of the respective parameter refers to the scaling in the row direction, while the second value refers to the scaling in the column direction.

Note that in `determine_shape_model_params` some parameters appear that can also be determined automatically ([NumLevels](#), [Optimization](#), [Contrast](#), [MinContrast](#)). If these parameters should not be determined automatically, i.e., their name is not passed in [Parameters](#), the corresponding parameters must contain valid values and must not be set to 'auto'. In contrast, if these parameters are to be determined automatically,

their values are treated in the following way: If the optimization or the (hysteresis) contrast is to be determined automatically, i.e., `Parameters` contains the value `'optimization'` or `'contrast'` (`'contrast_hyst'`), the values passed in `Optimization` and `Contrast` are ignored. In contrast, if the maximum number of pyramid levels or the minimum contrast is to be determined automatically, i.e., `Parameters` contains the value `'num_levels'` or `'min_contrast'`, you can let HALCON determine suitable values and at the same time specify an upper or lower boundary, respectively:

If the maximum number of pyramid levels should be specified in advance, `NumLevels` can be set to the particular value. If in this case `Parameters` contains the value `'num_levels'`, the computed number of pyramid levels is at most `NumLevels`. If `NumLevels` is set to `'auto'` (or 0 for backwards compatibility), the number of pyramid levels is determined without restrictions as large as possible.

If the minimum contrast should be specified in advance, `MinContrast` can be set to the particular value. If in this case `Parameters` contains the value `'min_contrast'`, the computed minimum contrast is at least `MinContrast`. If `MinContrast` is set to `'auto'`, the minimum contrast is determined without restrictions.

Attention

In some cases, the maximum number of pyramid levels that is returned by `determine_shape_model_params` is higher than the number of levels that are actually used in the shape model. The latter can be queried by using `get_shape_model_params` after creating the model. This might happen if the model is created by using `create_scaled_shape_model` or `create_aniso_shape_model` and `ScaleMin`, `ScaleRMin`, or `ScaleCMin` is below 1.0.

Parameters

- ▷ **Template** (input_object) (multichannel-)image $\leadsto$ object : byte / uint2
Input image whose domain will be used to create the model.
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer / string
Maximum number of pyramid levels.
Default: 'auto'
List of values: `NumLevels` $\in$ {'auto', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the model.
Default: -0.39
Suggested values: `AngleStart` $\in$ {-3.14, -1.57, -0.79, -0.39, -0.20, 0.0}
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: `AngleExtent` $\in$ {6.29, 3.14, 1.57, 0.79, 0.39}
Restriction: `AngleExtent` $\geq$ 0
- ▷ **ScaleMin** (input_control) number(-array) $\leadsto$ real
Minimum scale of the model.
Default: 0.9
Suggested values: `ScaleMin` $\in$ {0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: `ScaleMin` $>$ 0
- ▷ **ScaleMax** (input_control) number(-array) $\leadsto$ real
Maximum scale of the model.
Default: 1.1
Suggested values: `ScaleMax` $\in$ {1.0, 1.1, 1.2, 1.3, 1.4, 1.5}
Restriction: `ScaleMax` $\geq$ `ScaleMin`
- ▷ **Optimization** (input_control) string $\leadsto$ string
Kind of optimization.
Default: 'auto'
List of values: `Optimization` $\in$ {'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high'}
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: 'use_polarity'
List of values: `Metric` $\in$ {'use_polarity', 'ignore_global_polarity', 'ignore_local_polarity', 'ignore_color_polarity'}

- ▷ **Contrast** (input_control) number(-array) $\leadsto$ integer / string
Threshold or hysteresis thresholds for the contrast of the object in the template image and optionally minimum size of the object parts.
Default: 'auto'
Suggested values: Contrast $\in$ {'auto', 'auto_contrast', 'auto_contrast_hyst', 'auto_min_size', 10, 20, 30, 40, 60, 80, 100, 120, 140, 160}
- ▷ **MinContrast** (input_control) integer $\leadsto$ integer / string
Minimum contrast of the objects in the search images.
Default: 'auto'
Suggested values: MinContrast $\in$ {'auto', 1, 2, 3, 5, 7, 10, 20, 30, 40}
Restriction: MinContrast < Contrast
- ▷ **Parameters** (input_control) string(-array) $\leadsto$ string
Parameters to be determined automatically.
Default: 'all'
List of values: Parameters $\in$ {'all', 'num_levels', 'angle_step', 'scale_step', 'scale_r_step', 'scale_c_step', 'optimization', 'contrast', 'contrast_hyst', 'min_size', 'min_contrast'}
- ▷ **ParameterName** (output_control) string-array $\leadsto$ string
Name of the automatically determined parameter.
- ▷ **ParameterValue** (output_control) number-array $\leadsto$ real / integer
Value of the automatically determined parameter.

Result

If the parameters are valid, the operator `determine_shape_model_params` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised. If the parameters `NumLevels` and `Contrast` are chosen such that the model contains too few points, or the input image does not contain a sufficient number of significant features, the error 8510 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`draw_region`, `reduce_domain`, `threshold`

Possible Successors

`create_generic_shape_model`

Module

Matching

```
find_aniso_shape_model ( Image : : ModelID, AngleStart,
    AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax,
    MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels,
    Greediness : Row, Column, Angle, ScaleR, ScaleC, Score )
```

Find the best matches of an anisotropically scaled shape model in an image.

The operator `find_aniso_shape_model` finds the best `NumMatches` instances of the anisotropically scaled shape model `ModelID` in the input image `Image`. The model must have been created previously by calling `create_aniso_shape_model` or `read_shape_model`.

The position, rotation, and scale in the row and column direction of the found instances of the model are returned in `Row`, `Column`, `Angle`, `ScaleR`, and `ScaleC`. Additionally, the score of each found instance is returned in `Score`.

Input parameters in detail

Image and its domain: The domain of the image `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape

model with `create_aniso_shape_model`. A different origin set with `set_shape_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with `set_system('border_shape_models', 'true')` for all models or with `set_shape_model_param(ModelID, 'border_shape_models', 'true')` for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.

AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax: The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. The parameters `ScaleRMin`, `ScaleRMax`, `ScaleCMin`, and `ScaleCMax` determine the range of scales in the row and column directions for which the model is searched. If necessary, both ranges are clipped to the range given when the model was created with `create_aniso_shape_model`. In particular, this means that the angle ranges of the model and the search must overlap.

If in `ModelID` a model is passed that was created by using `create_shape_model` or `create_scaled_shape_model` then the model is searched with an isotropic scaling of 1.0 or with an isotropic scaling within the range from `ScaleRMin` to `ScaleRMax`, respectively. In this case, for `ScaleR` and `ScaleC` identical values are returned.

Note that in some cases instances with a rotation or scale that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. `AngleStart` and `AngleExtent` as well as `ScaleRMin/ScaleCMin` and `ScaleRMax/ScaleCMax` are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified ranges.

MinScore: The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is. If the model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below `MinScore` are found.

In case that the shape model has been extended by clutter parameters with `set_shape_model_clutter` and thus `'use_clutter'` is enabled, `MinScore` expects a second value which determines what clutter value a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0. Changing this second value does not influence the runtime.

NumMatches: The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on `NumMatches`. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for `NumMatches` set to 1 might be different from the match with the highest score returned when setting `NumMatches` to 0 or > 1. If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise `NumMatches`, and then select the match with the highest score.

In case that the shape model has been extended by clutter parameters using `set_shape_model_clutter`, `NumMatches` also considers the second value passed in `MinScore`: If more than `NumMatches` instances with a score greater than the first entry of `MinScore` and a clutter score smaller than the second entry of `MinScore` are found in the image, only the best `NumMatches` instances with respect to clutter are returned. Still, `MinScore` takes precedence over `NumMatches` and

`NumMatches` must be set to 0 if all model instances fulfilling the conditions imposed by `MinScore` should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap` = 0, the found instances may not overlap at all, while for `MaxOverlap` = 1 all instances are returned.

SubPixel: The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to 'none' (or 'false' for backwards compatibility) the model's pose is only determined with pixel accuracy and the angle and scale resolution that was specified with `create_aniso_shape_model`. If `SubPixel` is set to 'interpolation' (or 'true') the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model's pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model's pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode requires additional computation time. The different modes for least-squares adjustment ('least_squares', 'least_squares_high', and 'least_squares_very_high') can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, `SubPixel` should be set to 'interpolation'. If least-squares adjustment is desired, 'least_squares' should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter `SubPixel`. The deformation must be specified in pixels. This can be done by passing the optional parameter value 'max_deformation' followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value 'max_deformation 2' must be passed in `SubPixel` in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value 'max_deformation 0' corresponds to a search without allowing deformations, i.e., the behavior is the same as if no 'max_deformation' is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if 'max_deformation' and `AngleExtent` are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either 'max_deformation' or `AngleExtent` to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if 'least_squares', 'least_squares_high', or 'least_squares_very_high' (see above) is chosen for the subpixel extraction (in comparison to 'none' or 'interpolation'). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

NumLevels: The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the shape model was created with `create_aniso_shape_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_aniso_shape_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_aniso_shape_model` may be too high. The consequence may be that some matches that may

have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_shape_model_params` and then use a slightly lower value in `find_aniso_shape_model`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of `[4,2]` for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, `SubPixel` should be set to at least `'least_squares'`. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called 'increased tolerance mode', the lowest pyramid level must be specified negatively in `NumLevels`. If, e.g., `NumLevels` is set to `[4,-2]`, the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level. This means that an instance of the shape model is searched on the pyramid level 2. If no instance of the model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If the `ModelID` was adapted with `adapt_shape_model_high_noise` the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing two values to `NumLevels` and explicitly setting the lowest pyramid level.

Greediness: The parameter `Greediness` determines how "greedily" the search should be carried out. If `Greediness` = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If `Greediness` = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For `Greediness` = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for `Greediness` = 0.9.

Output parameters in detail

Row, Column, Angle, ScaleR, ScaleC: The position, rotation, and scale in the row and column direction of the found instances of the model are returned in `Row`, `Column`, `Angle`, `ScaleR`, and `ScaleC`. The coordinates `Row` and `Column` are related to the position of the origin of the shape model in the search image. However, `Row` and `Column` do not exactly correspond to this position. Instead, `find_aniso_shape_model` returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model contours. (This has to do with the way HALCON transforms iconic objects, see `affine_trans_pixel`). The example below shows how to create the transformation matrix for alignment of the found matches and how to use it to display them in the search image.

By default, the model origin is the center of gravity of the domain (region) of the image that was used to create the shape model with `create_aniso_shape_model`. A different origin can be set with `set_shape_model_origin`.

Score: The score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape model has been extended by clutter parameters using `set_shape_model_clutter`, following the above values `Score` also returns the clutter scores

of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter score will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter score is 0.2 for the first instance and 0.1 for the second instance, `Score = [0.9, 0.8, 0.2, 0.1]` is returned. Please note that of all shape-based matching results, clutter scores are affected the most when a variation of illumination occurs.

Specifying a timeout

Using the operator `set_shape_model_param` you can specify a 'timeout' for `find_aniso_shape_model`. If `find_aniso_shape_model` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling ranges specified by `ScaleRMin`, `ScaleRMax`, `ScaleCMin`, and `ScaleCMax`, `find_aniso_shape_model` needs a significant amount of time to free cached transformations if the shape model is not pregenerated. As this transformations have to be freed after a timeout occurs, the runtime of `find_aniso_shape_model` exceeds the value of the specified 'timeout' by this time.

Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter [Transformations / 2D Transformations](#).

Parameters

- ▷ **Image** (input_object) (multichannel-)image $\leadsto$ object : byte / uint2
Input image in which the model should be found.
- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.
- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the model.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
- ▷ **ScaleRMin** (input_control) number $\leadsto$ real
Minimum scale of the model in the row direction.
Default: 0.9
Suggested values: ScaleRMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleRMin > 0
- ▷ **ScaleRMax** (input_control) number $\leadsto$ real
Maximum scale of the model in the row direction.
Default: 1.1
Suggested values: ScaleRMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleRMax $\geq$ ScaleRMin
- ▷ **ScaleCMin** (input_control) number $\leadsto$ real
Minimum scale of the model in the column direction.
Default: 0.9
Suggested values: ScaleCMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleCMin > 0
- ▷ **ScaleCMax** (input_control) number $\leadsto$ real
Maximum scale of the model in the column direction.
Default: 1.1
Suggested values: ScaleCMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleCMax $\geq$ ScaleCMin

- ▷ **MinScore** (input_control) real(-array) $\leadsto$ *real*
Minimum score of the instances of the model to be found.
Default: 0.5
Suggested values: MinScore $\in$ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control) integer $\leadsto$ *integer*
Number of instances of the model to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in$ {0, 1, 2, 3, 4, 5, 10, 20}
- ▷ **MaxOverlap** (input_control) real $\leadsto$ *real*
Maximum overlap of the instances of the model to be found.
Default: 0.5
Suggested values: MaxOverlap $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **SubPixel** (input_control) string(-array) $\leadsto$ *string*
Subpixel accuracy if not equal to 'none'.
Default: 'least_squares'
Suggested values: SubPixel $\in$ {'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3', 'max_deformation 4', 'max_deformation 5', 'max_deformation 6'}
- ▷ **NumLevels** (input_control) integer(-array) $\leadsto$ *integer*
Number of pyramid levels used in the matching (and lowest pyramid level to use if |NumLevels| = 2).
Default: 0
List of values: NumLevels $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **Greediness** (input_control) real $\leadsto$ *real*
"Greediness" of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: Greediness $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{Greediness} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **Row** (output_control) point.y-array $\leadsto$ *real*
Row coordinate of the found instances of the model.
- ▷ **Column** (output_control) point.x-array $\leadsto$ *real*
Column coordinate of the found instances of the model.
- ▷ **Angle** (output_control) angle.rad-array $\leadsto$ *real*
Rotation angle of the found instances of the model.
- ▷ **ScaleR** (output_control) number-array $\leadsto$ *real*
Scale of the found instances of the model in the row direction.
- ▷ **ScaleC** (output_control) number-array $\leadsto$ *real*
Scale of the found instances of the model in the column direction.
- ▷ **Score** (output_control) real-array $\leadsto$ *real*
Score of the found instances of the model.

Example

```
create_aniso_shape_model (ImageReduced, 0, rad(-15), rad(30), 0, \
                        0.9, 1.1, 0, 0.9, 1.1, 0, 'none', \
                        'use_polarity', 30, 10, ModelID)
get_shape_model_contours (ModelXLD, ModelID, 1)
find_aniso_shape_model (SearchImage, ModelID, rad(-15), rad(30), \
                        0.9, 1.1, 0.9, 1.1, 0.5, 1, 0.5, 'interpolation', \
                        0, 0, Row, Column, Angle, ScaleR, ScaleC, Score)
* Create transformation matrix
```

```

hom_mat2d_identity (HomMat2DIdentity)
hom_mat2d_scale (HomMat2DIdentity, ScaleR, ScaleC, 0, 0, HomMat2DScale)
hom_mat2d_rotate (HomMat2DScale, Angle, 0, 0, HomMat2DRotate)
hom_mat2d_translate (HomMat2DRotate, Row, Column, HomMat2DObject)
* Calculate true position of the model origin in the search image
affine_trans_pixel (HomMat2DObject, 0, 0, RowObject, ColObject)
* Display results
dev_display_shape_matching_results (ModelID, 'red', Row, Column, Angle, \
                                   ScaleR, ScaleC, 0)

```

Result

If the parameter values are correct, the operator `find_aniso_shape_model` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Matching

```

find_aniso_shape_models ( Image : : ModelIDs, AngleStart,
                          AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, ScaleCMax,
                          MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels,
                          Greediness : Row, Column, Angle, ScaleR, ScaleC, Score, Model )

```

Find the best matches of multiple anisotropically scaled shape models.

The operator `find_aniso_shape_models` finds the best `NumMatches` instances of the anisotropically scaled shape models that are passed in `ModelIDs` in the input image `Image`. The models must have been created previously by calling `create_aniso_shape_model` or `read_shape_model`. In contrast to `find_aniso_shape_model`, multiple models can be searched in the same image in one call.

The position, rotation, and scale in the row and column direction of the found instances of the model are returned in `Row`, `Column`, `Angle`, `ScaleR`, and `ScaleC`. The score of each found instance is returned in `Score`. The type of the found instances of the models is returned in `Model`. For details see respective sections below.

Characteristics of the parameter semantics

Compared to `find_aniso_shape_model`, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or must contain the same number of elements as `ModelIDs`, in which case each parameter element refers to the corresponding element in `ModelIDs`. (`NumLevels` may also contain either two or twice the number of elements as `ModelIDs`.) More details can be found below in the sections containing information for the respective parameters. Note that a call to `find_aniso_shape_models` with multiple values for `ModelIDs`, `NumMatches`

and `MaxOverlap` has the same effect as multiple independent calls to `find_aniso_shape_model` with the respective parameters. However, a single call to `find_aniso_shape_models` is considerably more efficient.

Input parameters in detail

Image and its domain: The domain of the `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with `create_aniso_shape_model`. A different origin set with `set_shape_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with `set_system('border_shape_models', 'true')` for all models or with `set_shape_model_param(ModelID, 'border_shape_models', 'true')` for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.

As usual, the domain of the input `Image` is used to restrict the search space for the reference point of the models `ModelIDs`. Consistent with the above semantics, the input `Image` can therefore contain a single image object or an image object tuple containing multiple image objects. If `Image` contains a single image object, its domain is used as the region of interest for all models in `ModelIDs`. If `Image` contains multiple image objects, each domain is used as the region of interest for the corresponding model in `ModelIDs`. In this case, the images have to be identical except for their domains, i.e., their pointers have to be identical (the pointers can be checked using `get_image_pointer1`). As a consequence, `Image` cannot be constructed in an arbitrary manner using `concat_obj`, but must be created from the same image using `add_channels` or equivalent calls. If this is not the case, an error message is returned.

AngleStart, AngleExtent, ScaleRMin, ScaleRMax, ScaleCMin, and ScaleCMax: The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. The parameters `ScaleRMin`, `ScaleRMax`, `ScaleCMin`, and `ScaleCMax` determine the range of scales in the row and column directions for which the model is searched. If necessary, both ranges are clipped to the range given when the model was created with `create_aniso_shape_model`. In particular, this means that the angle ranges of the model and the search must overlap.

If in `ModelIDs` a model is passed that was created by using `create_shape_model` or `create_scaled_shape_model` then the model is searched with an isotropic scaling of 1.0 or with an isotropic scaling within the range from `ScaleRMin` to `ScaleRMax`, respectively. In this case, for `ScaleR` and `ScaleC` identical values are returned.

Note that in some cases instances with a rotation or scale that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. `AngleStart` and `AngleExtent` as well as `ScaleRMin/ScaleCMin` and `ScaleRMax/ScaleCMax` are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified ranges.

MinScore: The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is. If the model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below `MinScore` are found.

If a single value is passed in `MinScore`, this value is applied to found instances of all models. If, on the other hand, `MinScore` contains multiple values, the values are applied separately for the respective model.

In case that the shape models have been extended by clutter parameters with `set_shape_model_clutter` and thus `'use_clutter'` is enabled, `MinScore` expects for each minimum score an additional value which determines what clutter score a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as

high as the runtime without clutter parameters and `NumMatches` set to 0. Changing this second value does not influence the runtime. Note that the different shape models must have the same value for `'use_clutter'`.

If the maximum clutter is specified separately for each model, which is needed if also the minimum score is set for each model individually, `MinScore` must contain twice the number of elements as `ModelIDs`. In this case, the minimum score and the maximum clutter must be specified interleaved in `MinScore`. If, for example, two models are specified in `ModelIDs`, the minimum score is 0.9 for the first model and 0.8 for the second model, and the maximum clutter is 0.1 for the first model and 0.2 for the second model, `MinScore = [0.9, 0.1, 0.8, 0.2]` must be selected.

NumMatches: The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on `NumMatches`. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for `NumMatches` set to 1 might be different from the match with the highest score returned when setting `NumMatches` to 0 or > 1.

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise `NumMatches`, and then select the match with the highest score.

In case that the shape models have been extended by clutter parameters using `set_shape_model_clutter`, `NumMatches` also considers the second value passed in `MinScore`: If more than `NumMatches` instances with a score greater than the first entry of `MinScore` and a clutter score smaller than the second entry of `MinScore` are found in the image, only the best `NumMatches` instances with respect to clutter are returned. Still, `MinScore` takes precedence over `NumMatches` and `NumMatches` must be set to 0 if all model instances fulfilling the conditions imposed by `MinScore` should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0.

If `NumMatches` contains one element, `find_aniso_shape_models` returns the best `NumMatches` instances of the model irrespective of the type of the model. If, for example, two models are passed in `ModelIDs` and `NumMatches = 2` is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, `NumMatches` contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in `NumMatches`. If, for example, `NumMatches = [1, 1]` is selected, one instance of the first model and one instance of the second model is returned.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap = 0`, the found instances may not overlap at all, while for `MaxOverlap = 1` all instances are returned.

If a single value is passed in `MaxOverlap`, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in `MaxOverlap`, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

SubPixel: The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to `'none'` (or `'false'` for backwards compatibility) the model's pose is only determined with pixel accuracy and the angle and scale resolution that was specified with `create_aniso_shape_model`. If `SubPixel` is set to `'interpolation'` (or `'true'`) the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model's pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model's pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to `'interpolation'`, this mode

requires additional computation time. The different modes for least-squares adjustment (*'least_squares'*, *'least_squares_high'*, and *'least_squares_very_high'*) can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, `SubPixel` should be set to *'interpolation'*. If least-squares adjustment is desired, *'least_squares'* should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter `SubPixel`. The deformation must be specified in pixels. This can be done by passing the optional parameter value *'max_deformation '* followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value *'max_deformation 2'* must be passed in `SubPixel` in addition to the above described mode for the subpixel extraction, i.e., for example [*'least_squares', 'max_deformation 2'*]. Passing the value *'max_deformation 0'* corresponds to a search without allowing deformations, i.e., the behavior is the same as if no *'max_deformation '* is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if *'max_deformation'* and `AngleExtent` are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either *'max_deformation'* or `AngleExtent` to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if *'least_squares'*, *'least_squares_high'*, or *'least_squares_very_high'* (see above) is chosen for the subpixel extraction (in comparison to *'none'* or *'interpolation'*). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

If the subpixel extraction and/or the maximum object deformation is specified separately for each model, for each model passed in `ModelIDs` exactly one value for the subpixel extraction must be passed in `SubPixel`. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain model no value for the maximum object deformation is passed, the model is searched without taking deformations into account. For example, if two models are passed in `ModelIDs` and for the first model the subpixel extraction is set to *'interpolation'* and no object deformations are allowed and for the second model the subpixel extraction is set to *'least_squares'* and a maximum object deformation of 3 pixels is allowed, then the tuple [*'interpolation', 'least_squares', 'max_deformation 3'*] must be passed in `SubPixel`. Alternatively, the equivalent tuple [*'interpolation', 'max_deformation 0', 'least_squares', 'max_deformation 3'*] may be passed.

NumLevels: The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the shape model was created with `create_aniso_shape_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_aniso_shape_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_aniso_shape_model` may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_shape_model_params` and then use a slightly lower value in `find_aniso_shape_models`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of [4,2] for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is

desired, `SubPixel` should be set to at least *'least_squares'*. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, `NumLevels` must contain twice the number of elements as `ModelIDs`. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in `NumLevels`. If, for example, two models are specified in `ModelIDs`, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model, `NumLevels = [5, 2, 4, 1]` must be selected. If exactly two models are specified in `ModelIDs`, a special case occurs. If in this case the lowest pyramid level is to be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in `NumLevels` is interpreted as the explicit specification of the number of pyramid levels for the two models.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called 'increased tolerance mode', the lowest pyramid level must be specified negatively in `NumLevels`. If, e.g., `NumLevels` is set to `[5, 2, 4, -1]`, the lowest pyramid level for the first model is set to 2. If no instance of the first model can be found on this pyramid level, no result will be returned for this model. For the second shape model, the lowest pyramid level is set to `-1`. Therefore, an instance of the shape model is searched on the pyramid level 1. If no instance of the second model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If a model was adapted with `adapt_shape_model_high_noise` the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing explicitly the lowest pyramid level as described above.

Greediness: The parameter `Greediness` determines how "greedily" the search should be carried out. If `Greediness = 0`, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If `Greediness = 1`, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For `Greediness = 1`, the maximum search speed is achieved. In almost all cases, the shape model will always be found for `Greediness = 0.9`.

Output parameters in detail

Row, Column, Angle, ScaleR, ScaleC: The position, rotation, and scale in the row and column direction of the found instances of the model are returned in `Row`, `Column`, `Angle`, `ScaleR`, and `ScaleC`. The coordinates `Row` and `Column` are the coordinates of the origin of the shape model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the shape model with `create_aniso_shape_model`. A different origin can be set with `set_shape_model_origin`.

Note that the coordinates `Row` and `Column` do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for `find_aniso_shape_model` shows how to create this matrix and use it to display the model at the found position in the search image.

Note also that for visualizing the model at the found position, also the procedure `dev_display_shape_matching_results` can be used.

Score: The score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape models have been extended by clutter parameters using `set_shape_model_clutter`, following the above values `Score` also returns the clutter scores of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter score will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter score is 0.2 for the first instance and 0.1 for the second instance, `Score = [0.9, 0.8, 0.2, 0.1]` is returned. Please note that of all shape-based matching results, clutter scores are affected the most when a variation of illumination occurs.

Model: The type of the found instances of the models is returned in `Model`. The elements of `Model` are indices into the tuple `ModelIDs`, i.e., they can contain values from 0 to $|\text{ModelIDs}| - 1$. Hence, a value of 0 in an element of `Model` corresponds to an instance of the first model in `ModelIDs`.

Specifying a timeout

Using the operator `set_shape_model_param` you can specify a 'timeout' for `find_aniso_shape_models`. If the shape models referenced by `ModelIDs` hold different values for 'timeout', `find_aniso_shape_models` uses the smallest one. If `find_aniso_shape_models` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling ranges specified by `ScaleRMin`, `ScaleRMax`, `ScaleCMin` and `ScaleCMax`, `find_aniso_shape_models` needs a significant amount of time to free cached transformations if the shape model is not pregenerated. As this transformations have to be freed after a timeout occurs, the runtime of `find_aniso_shape_models` exceeds the value of the specified 'timeout' by this time.

MinContrast with multiple models

Please note, that the different models that are given with the parameter `ModelIDs` should have been created with the same value of `MinContrast`. If they were created with different values for `MinContrast`, `find_aniso_shape_models` will use the smallest of these values.

Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter [Transformations / 2D Transformations](#).

Parameters

- ▷ **Image** (input_object)(multichannel-)image(-array) $\leadsto$ *object* : byte / uint2
Input image in which the models should be found.
- ▷ **ModelIDs** (input_control) shape_model(-array) $\leadsto$ *handle*
Handle of the models.
- ▷ **AngleStart** (input_control) angle.rad(-array) $\leadsto$ *real*
Smallest rotation of the models.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad(-array) $\leadsto$ *real*
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
- ▷ **ScaleRMin** (input_control) number(-array) $\leadsto$ *real*
Minimum scale of the models in the row direction.
Default: 0.9
Suggested values: ScaleRMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleRMin > 0
- ▷ **ScaleRMax** (input_control) number(-array) $\leadsto$ *real*
Maximum scale of the models in the row direction.
Default: 1.1
Suggested values: ScaleRMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleRMax $\geq$ ScaleRMin

- ▷ **ScaleCMin** (input_control) number(-array) $\leadsto$ *real*
Minimum scale of the models in the column direction.
Default: 0.9
Suggested values: ScaleCMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleCMin > 0
- ▷ **ScaleCMax** (input_control) number(-array) $\leadsto$ *real*
Maximum scale of the models in the column direction.
Default: 1.1
Suggested values: ScaleCMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleCMax $\geq$ ScaleCMin
- ▷ **MinScore** (input_control) real(-array) $\leadsto$ *real*
Minimum score of the instances of the models to be found.
Default: 0.5
Suggested values: MinScore $\in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control) integer(-array) $\leadsto$ *integer*
Number of instances of the models to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in \{0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **MaxOverlap** (input_control) real(-array) $\leadsto$ *real*
Maximum overlap of the instances of the models to be found.
Default: 0.5
Suggested values: MaxOverlap $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **SubPixel** (input_control) string(-array) $\leadsto$ *string*
Subpixel accuracy if not equal to 'none'.
Default: 'least_squares'
Suggested values: SubPixel $\in \{'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation_1', 'max_deformation_2', 'max_deformation_3', 'max_deformation_4', 'max_deformation_5', 'max_deformation_6'\}$
- ▷ **NumLevels** (input_control) integer(-array) $\leadsto$ *integer*
Number of pyramid levels used in the matching (and lowest pyramid level to use if $|\text{NumLevels}| = 2$).
Default: 0
List of values: NumLevels $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$
- ▷ **Greediness** (input_control) real(-array) $\leadsto$ *real*
"Greediness" of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: Greediness $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{Greediness} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **Row** (output_control) point.y-array $\leadsto$ *real*
Row coordinate of the found instances of the models.
- ▷ **Column** (output_control) point.x-array $\leadsto$ *real*
Column coordinate of the found instances of the models.
- ▷ **Angle** (output_control) angle.rad-array $\leadsto$ *real*
Rotation angle of the found instances of the models.
- ▷ **ScaleR** (output_control) number-array $\leadsto$ *real*
Scale of the found instances of the models in the row direction.
- ▷ **ScaleC** (output_control) number-array $\leadsto$ *real*
Scale of the found instances of the models in the column direction.
- ▷ **Score** (output_control) real-array $\leadsto$ *real*
Score of the found instances of the models.

▷ **Model** (output_control) integer-array $\leadsto$ integer
Index of the found instances of the models.

Example

```
read_image (Image, 'pcb_focus/pcb_focus_telecentric_061')
gen_rectangle1 (ROI_0, 236, 241, 313, 321)
gen_circle (ROI_1, 281, 653, 41)
reduce_domain (Image, ROI_0, ImageReduced1)
reduce_domain (Image, ROI_1, ImageReduced2)
create_aniso_shape_model (ImageReduced1, 'auto', -0.39, 0.79, 'auto', 0.9, \
                          1.1, 'auto', 0.9, 1.1, 'auto', 'auto', \
                          'use_polarity', 'auto', 'auto', ModelID1)
create_aniso_shape_model (ImageReduced2, 'auto', -0.39, 0.79, 'auto', 0.9, \
                          1.1, 'auto', 0.9, 1.1, 'auto', 'auto', \
                          'use_polarity', 'auto', 'auto', ModelID2)
ModelIDs:=[ModelID1, ModelID2]

                        0.5, 1, 0.5, 'least_squares', 0, 0.9, Row, Column, \
                        Angle, ScaleR, ScaleC, Score, Model)

* Display results
dev_display_shape_matching_results (ModelIDs, 'red', Row, Column, Angle, \
                                   ScaleR, ScaleC, Model)
```

Result

If the parameter values are correct, the operator `find_aniso_shape_models` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Matching

find_generic_shape_model (SearchImage : : ModelID : MatchResultID,
NumMatchResult)

Find the best matches of one or multiple shape models in an image.

The operator `find_generic_shape_model` finds the best instances of one or multiple shape models passed in `ModelID` in the input image `SearchImage`. The found matches are returned in `MatchResultID` and can be queried using `get_generic_shape_model_result` and `get_generic_shape_model_result_object`. The number of found matches is returned in

`NumMatchResult`. The model can be parameterized using `set_generic_shape_model_param` and `set_generic_shape_model_object`, through which one can control the search.

The domain of the input image `SearchImage` sets the ROI for the search. It limits the search space as it is considered as boundary for the center of gravity of `ModelID` in order to accelerate the matching process. For information on passing a tuple of images to `SearchImage` see below. Furthermore, the search space is limited by the size of `SearchImage`. By default, `ModelID` is only searched within those points of the domain, in which `ModelID` fits completely. Hence, `ModelID` will not be found if it exceeds the border of the image. This holds for all levels of the used image pyramid.

In rare cases which typically occur for artificial images, instances of `ModelID` cannot be found in an image, if they touch the border of the domain on any level of the image pyramid. As a rule of thumb, `ModelID` might not be found if its distance to an image border is smaller than $2^{NumLevels-1}$ pixels (where `NumLevels` is the number of pyramid levels). This behavior can be changed with `'border_shape_models'`, see `set_generic_shape_model_param`.

When searching multiple models, the search space can be restricted for all models simultaneously by passing a single image with reduced domain in `SearchImage`.

Alternatively, the search space can be restricted for each model individually by passing an object containing multiple image objects, one for each model in `ModelID`. The search space is determined by the domain of the corresponding image. Except the domain, the images have to be identical, i.e., the pointers of the image objects need to refer to the same image (thus they need to be identical). The pointers can be checked using `get_image_pointer1`.

When applying multiple models, different identifiers (`'model_identifier'`) have to be set for each model, so that each instance can be assigned to the shape model it has been found with. Otherwise an exception is raised.

Parameters

- ▷ **SearchImage** (input_object) (multichannel-)object(-array) $\leadsto$ *object*
Image in which the model is searched.
- ▷ **ModelID** (input_control) shape_model(-array) $\leadsto$ *handle*
Handle of the shape model.
- ▷ **MatchResultID** (output_control) generic_shape_model_result $\leadsto$ *handle*
Handle with the found matches.
- ▷ **NumMatchResult** (output_control) integer $\leadsto$ *integer*
Number of found matches.

Result

If the parameters are valid, the operator `find_generic_shape_model` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators. This operator modifies the state of the following input parameter:

- `ModelID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

Matching

```
find_scaled_shape_model ( Image : : ModelID, AngleStart,
    AngleExtent, ScaleMin, ScaleMax, MinScore, NumMatches,
    MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column,
    Angle, Scale, Score )
```

Find the best matches of an isotropically scaled shape model in an image.

The operator `find_scaled_shape_model` finds the best `NumMatches` instances of the isotropically scaled shape model `ModelID` in the input image `Image`. The model must have been created previously by calling `create_scaled_shape_model` or `read_shape_model`.

The position, rotation, and scale of the found instances of the model are returned in `Row`, `Column`, `Angle`, and `Scale`. The score of each found instance is returned in `Score`.

Input parameters in detail

Image and its domain: The domain of the image `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with `create_scaled_shape_model`. A different origin set with `set_shape_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with `set_system('border_shape_models','true')` for all models or with `set_shape_model_param(ModelID,'border_shape_models','true')` for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.

AngleStart, AngleExtent, ScaleMin, ScaleMax: The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. The parameters `ScaleMin` and `ScaleMax` determine the range of scales for which the model is searched. If necessary, both ranges are clipped to the range given when the model was created with `create_scaled_shape_model`. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation or scale that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. `AngleStart` and `AngleExtent` as well as `ScaleMin` and `ScaleMax` are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified ranges.

MinScore: The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is. If the model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below `MinScore` are found.

In case that the shape model has been extended by clutter parameters with `set_shape_model_clutter` and thus `'use_clutter'` is enabled, `MinScore` expects a second value which determines what clutter score a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0. Changing this second value does not influence the runtime.

NumMatches: The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on `NumMatches`. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for `NumMatches` set to 1 might be different from the match with the highest score returned when setting `NumMatches` to 0 or > 1.

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise `NumMatches`, and then select the match with the highest score.

In case that the shape model has been extended by clutter parameters using `set_shape_model_clutter`, `NumMatches` also considers the second value passed in `MinScore`: If more than `NumMatches` instances with a score greater than the first entry of `MinScore` and a clutter score smaller than the second entry of `MinScore` are found in the image, only the best `NumMatches` instances with respect to clutter are returned. Still, `MinScore` takes precedence over `NumMatches` and `NumMatches` must be set to 0 if all model instances fulfilling the conditions imposed by `MinScore` should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap` = 0, the found instances may not overlap at all, while for `MaxOverlap` = 1 all instances are returned.

SubPixel: The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to 'none' (or 'false' for backwards compatibility) the model's pose is only determined with pixel accuracy and the angle and scale resolution that was specified with `create_scaled_shape_model`. If `SubPixel` is set to 'interpolation' (or 'true') the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model's pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model's pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode requires additional computation time. The different modes for least-squares adjustment ('least_squares', 'least_squares_high', and 'least_squares_very_high') can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, `SubPixel` should be set to 'interpolation'. If least-squares adjustment is desired, 'least_squares' should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter `SubPixel`. The deformation must be specified in pixels. This can be done by passing the optional parameter value 'max_deformation' followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value 'max_deformation 2' must be passed in `SubPixel` in addition to the above described mode for the subpixel extraction, i.e., for example ['least_squares', 'max_deformation 2']. Passing the value 'max_deformation 0' corresponds to a search without allowing deformations, i.e., the behavior is the same as if no 'max_deformation' is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if 'max_deformation' and `AngleExtent` are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either 'max_deformation' or `AngleExtent` to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if 'least_squares', 'least_squares_high',

or *'least_squares_very_high'* (see above) is chosen for the subpixel extraction (in comparison to *'none'* or *'interpolation'*). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

NumLevels: The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the shape model was created with `create_scaled_shape_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_scaled_shape_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_scaled_shape_model` may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_shape_model_params` and then use a slightly lower value in `find_scaled_shape_model`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of `[4,2]` for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, `SubPixel` should be set to at least *'least_squares'*. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called 'increased tolerance mode', the lowest pyramid level must be specified negatively in `NumLevels`. If, e.g., `NumLevels` is set to `[4,-2]`, the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level. This means that an instance of the shape model is searched on the pyramid level 2. If no instance of the model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If the `ModelID` was adapted with `adapt_shape_model_high_noise` the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing two values to `NumLevels` and explicitly setting the lowest pyramid level.

Greediness: The parameter `Greediness` determines how "greedily" the search should be carried out. If `Greediness` = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If `Greediness` = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For `Greediness` = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for `Greediness` = 0.9.

Output parameters in detail

Row, Column, Angle, and Scale: The position, rotation, and scale of the found instances of the model are returned in `Row`, `Column`, `Angle`, and `Scale`. The coordinates `Row` and `Column` are related to the position of the origin of the shape model in the search image. However, `Row` and `Column` do not exactly correspond to this position. Instead, `find_scaled_shape_model` returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model contours.

(This has to do with the way HALCON transforms iconic objects, see [affine_trans_pixel](#)). The example below shows how to create the transformation matrix for alignment of the found matches and how to use it to display them in the search image.

By default, the model origin is the center of gravity of the domain (region) of the image that was used to create the shape model with [create_shape_model](#). A different origin can be set with [set_shape_model_origin](#).

Score: The score of each found instance is returned in [Score](#). The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape model has been extended by clutter parameters using [set_shape_model_clutter](#), following the above values [Score](#) also returns the clutter scores of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter score will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter score is 0.2 for the first instance and 0.1 for the second instance, [Score](#) = [0.9, 0.8, 0.2, 0.1] is returned. Please note that of all shape-based matching results, clutter scores are affected the most when a variation of illumination occurs.

Specifying a timeout

Using the operator [set_shape_model_param](#) you can specify a 'timeout' for [find_scaled_shape_model](#). If [find_scaled_shape_model](#) reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling range specified by [ScaleMin](#), and [ScaleMax](#), [find_scaled_shape_model](#) needs a significant amount of time to free cached transformations if the shape model is not pregenerated. As this transformations have to be freed after a timeout occurs, the runtime of [find_scaled_shape_model](#) exceeds the value of the specified 'timeout' by this time.

Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure [dev_display_shape_matching_results](#).

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter [Transformations / 2D Transformations](#).

Parameters

-
- ▷ **Image** (input_object)(multichannel-)image $\leadsto$ object : byte / uint2
Input image in which the model should be found.
 - ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.
 - ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the model.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
 - ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.78
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
 - ▷ **ScaleMin** (input_control) number $\leadsto$ real
Minimum scale of the model.
Default: 0.9
Suggested values: ScaleMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleMin > 0
 - ▷ **ScaleMax** (input_control) number $\leadsto$ real
Maximum scale of the model.
Default: 1.1
Suggested values: ScaleMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleMax $\geq$ ScaleMin

- ▷ **MinScore** (input_control) real(-array) $\leadsto$ *real*
Minimum score of the instances of the model to be found.
Default: 0.5
Suggested values: MinScore $\in$ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control) integer $\leadsto$ *integer*
Number of instances of the model to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in$ {0, 1, 2, 3, 4, 5, 10, 20}
- ▷ **MaxOverlap** (input_control) real $\leadsto$ *real*
Maximum overlap of the instances of the model to be found.
Default: 0.5
Suggested values: MaxOverlap $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **SubPixel** (input_control) string(-array) $\leadsto$ *string*
Subpixel accuracy if not equal to 'none'.
Default: 'least_squares'
Suggested values: SubPixel $\in$ {'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3', 'max_deformation 4', 'max_deformation 5', 'max_deformation 6'}
- ▷ **NumLevels** (input_control) integer(-array) $\leadsto$ *integer*
Number of pyramid levels used in the matching (and lowest pyramid level to use if |NumLevels| = 2).
Default: 0
List of values: NumLevels $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **Greediness** (input_control) real $\leadsto$ *real*
"Greediness" of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: Greediness $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{Greediness} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **Row** (output_control) point.y-array $\leadsto$ *real*
Row coordinate of the found instances of the model.
- ▷ **Column** (output_control) point.x-array $\leadsto$ *real*
Column coordinate of the found instances of the model.
- ▷ **Angle** (output_control) angle.rad-array $\leadsto$ *real*
Rotation angle of the found instances of the model.
- ▷ **Scale** (output_control) number-array $\leadsto$ *real*
Scale of the found instances of the model.
- ▷ **Score** (output_control) real-array $\leadsto$ *real*
Score of the found instances of the model.

Example

```
create_scaled_shape_model (ImageReduced, 0, rad(-45), rad(180), 0, \
                          0.9, 1.1, 0, 'none', 'use_polarity', \
                          30, 10, ModelID)
get_shape_model_contours (ModelXLD, ModelID, 1)
find_scaled_shape_model (SearchImage, ModelID, rad(-45), rad(180), \
                        0.9, 1.1, 0.5, 1, 0.5, 'interpolation', \
                        0, 0, Row, Column, Angle, Scale, Score)
* Create transformation matrix
vector_angle_to_rigid (0, 0, 0, Row, Column, Angle, HomMat2DTmp)
hom_mat2d_scale (HomMat2DTmp, Scale, Scale, Row, Column, HomMat2DObject)
```

```
* Calculate true position of the model origin in the search image
affine_trans_pixel (HomMat2DObject, 0, 0, RowObject, ColObject)
* Display results
dev_display_shape_matching_results (ModelID, 'red', Row, Column, Angle, \
                                   Scale, 1, 0)
```

Result

If the parameter values are correct, the operator `find_scaled_shape_model` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

Matching

<pre>find_scaled_shape_models (Image : : ModelIDs, AngleStart, AngleExtent, ScaleMin, ScaleMax, MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels, Greediness : Row, Column, Angle, Scale, Score, Model)</pre>

Find the best matches of multiple isotropically scaled shape models.

The operator `find_scaled_shape_models` finds the best `NumMatches` instances of the isotropically scaled shape models that are passed in `ModelIDs` in the input image `Image`. The models must have been created previously by calling `create_scaled_shape_model` or `read_shape_model`. In contrast to `find_scaled_shape_model`, multiple models can be searched in the same image in one call.

The position, rotation, and scale of the found instances of the model are returned in `Row`, `Column`, `Angle`, and `Scale`. The score of each found instance is returned in `Score`. The type of the found instances of the models is returned in `Model`. For details see respective sections below.

Characteristics of the parameter semantics

Compared to `find_scaled_shape_model`, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or must contain the same number of elements as `ModelIDs`, in which case each parameter element refers to the corresponding element in `ModelIDs`. (`NumLevels` may also contain either two or twice the number of elements as `ModelIDs`.) More details can be found below in the sections containing information for the respective parameters. Note that a call to `find_scaled_shape_models` with multiple values for `ModelIDs`, `NumMatches` and `MaxOverlap` has the same effect as multiple independent calls to `find_scaled_shape_model` with the respective parameters. However, a single call to `find_scaled_shape_models` is considerably more efficient.

Input parameters in detail

Image and its domain: The domain of the `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with `create_scaled_shape_model`. A different origin set with `set_shape_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with `set_system('border_shape_models', 'true')` for all models or with `set_shape_model_param(ModelID, 'border_shape_models', 'true')` for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.

As usual, the domain of the input `Image` is used to restrict the search space for the reference point of the models `ModelIDs`. Consistent with the above semantics, the input `Image` can therefore contain a single image object or an image object tuple containing multiple image objects. If `Image` contains a single image object, its domain is used as the region of interest for all models in `ModelIDs`. If `Image` contains multiple image objects, each domain is used as the region of interest for the corresponding model in `ModelIDs`. In this case, the images have to be identical except for their domains, i.e., their pointers have to be identical (the pointers can be checked using `get_image_pointer1`). As a consequence, `Image` cannot be constructed in an arbitrary manner using `concat_obj`, but must be created from the same image using `add_channels` or equivalent calls. If this is not the case, an error message is returned.

AngleStart, AngleExtent, ScaleMin, ScaleMax: The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. The parameters `ScaleMin` and `ScaleMax` determine the range of scales for which the model is searched. If necessary, both ranges are clipped to the range given when the model was created with `create_scaled_shape_model`. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation or scale that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. `AngleStart` and `AngleExtent` as well as `ScaleMin` and `ScaleMax` are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified ranges.

MinScore: The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is. If the model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below `MinScore` are found.

If a single value is passed in `MinScore`, this value is applied to found instances of all models. If, on the other hand, `MinScore` contains multiple values, the values are applied separately for the respective model.

In case that the shape models have been extended by clutter parameters with `set_shape_model_clutter` and thus `'use_clutter'` is enabled, `MinScore` expects for each minimum score an additional value which determines what clutter score a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0. Changing this second value does not influence the runtime. Note that the different shape models must have the same value for `'use_clutter'`.

If the maximum clutter is specified separately for each model, which is needed if also the minimum score is set for each model individually, `MinScore` must contain twice the number of elements as `ModelIDs`. In this case, the minimum score and the maximum clutter must be specified interleaved in `MinScore`. If, for example, two models are specified in `ModelIDs`, the minimum score is 0.9 for the first model and 0.8 for the second model, and the maximum clutter is 0.1 for the first model and 0.2 for the second model, `MinScore = [0.9, 0.1, 0.8, 0.2]` must be selected.

NumMatches: The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best

`NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on `NumMatches`. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for `NumMatches` set to 1 might be different from the match with the highest score returned when setting `NumMatches` to 0 or > 1.

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise `NumMatches`, and then select the match with the highest score.

In case that the shape models have been extended by clutter parameters using `set_shape_model_clutter`, `NumMatches` also considers the second value passed in `MinScore`: If more than `NumMatches` instances with a score greater than the first entry of `MinScore` and a clutter score smaller than the second entry of `MinScore` are found in the image, only the best `NumMatches` instances with respect to clutter are returned. Still, `MinScore` takes precedence over `NumMatches` and `NumMatches` must be set to 0 if all model instances fulfilling the conditions imposed by `MinScore` should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0.

If `NumMatches` contains one element, `find_scaled_shape_models` returns the best `NumMatches` instances of the model irrespective of the type of the model. If, for example, two models are passed in `ModelIDs` and `NumMatches` = 2 is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, `NumMatches` contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in `NumMatches`. If, for example, `NumMatches` = [1, 1] is selected, one instance of the first model and one instance of the second model is returned.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap` = 0, the found instances may not overlap at all, while for `MaxOverlap` = 1 all instances are returned.

If a single value is passed in `MaxOverlap`, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in `MaxOverlap`, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

SubPixel: The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to 'none' (or 'false' for backwards compatibility) the model's pose is only determined with pixel accuracy and the angle and scale resolution that was specified with `create_scaled_shape_model`. If `SubPixel` is set to 'interpolation' (or 'true') the position as well as the rotation and scale are determined with subpixel accuracy. In this mode, the model's pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model's pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode requires additional computation time. The different modes for least-squares adjustment ('least_squares', 'least_squares_high', and 'least_squares_very_high') can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, `SubPixel` should be set to 'interpolation'. If least-squares adjustment is desired, 'least_squares' should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter `SubPixel`. The deformation must be specified in pixels. This can be done by passing the optional parameter value 'max_deformation' followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be

deformed by up to 2 pixels with respect to the shape that is stored in the model, the value `'max_deformation 2'` must be passed in `SubPixel` in addition to the above described mode for the subpixel extraction, i.e., for example `['least_squares', 'max_deformation 2']`. Passing the value `'max_deformation 0'` corresponds to a search without allowing deformations, i.e., the behavior is the same as if no `'max_deformation'` is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if `'max_deformation'` and `AngleExtent` are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either `'max_deformation'` or `AngleExtent` to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if `'least_squares'`, `'least_squares_high'`, or `'least_squares_very_high'` (see above) is chosen for the subpixel extraction (in comparison to `'none'` or `'interpolation'`). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

If the subpixel extraction and/or the maximum object deformation is specified separately for each model, for each model passed in `ModelIDs` exactly one value for the subpixel extraction must be passed in `SubPixel`. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain model no value for the maximum object deformation is passed, the model is searched without taking deformations into account. For example, if two models are passed in `ModelIDs` and for the first model the subpixel extraction is set to `'interpolation'` and no object deformations are allowed and for the second model the subpixel extraction is set to `'least_squares'` and a maximum object deformation of 3 pixels is allowed, then the tuple `['interpolation', 'least_squares', 'max_deformation 3']` must be passed in `SubPixel`. Alternatively, the equivalent tuple `['interpolation', 'max_deformation 0', 'least_squares', 'max_deformation 3']` may be passed.

NumLevels: The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the shape model was created with `create_scaled_shape_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_scaled_shape_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_scaled_shape_model` may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_shape_model_params` and then use a slightly lower value in `find_scaled_shape_models`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of `[4,2]` for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, `SubPixel` should be set to at least `'least_squares'`. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, `NumLevels` must contain twice the number of elements as `ModelIDs`. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in `NumLevels`. If, for example, two models are specified in `ModelIDs`, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model, `NumLevels = [5, 2, 4, 1]` must be selected. If exactly two models are specified in `ModelIDs`, a special case occurs. If in this case the lowest pyramid level is to

be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in `NumLevels` is interpreted as the explicit specification of the number of pyramid levels for the two models.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called 'increased tolerance mode', the lowest pyramid level must be specified negatively in `NumLevels`. If, e.g., `NumLevels` is set to `[5,2,4,-1]`, the lowest pyramid level for the first model is set to 2. If no instance of the first model can be found on this pyramid level, no result will be returned for this model. For the second shape model, the lowest pyramid level is set to `-1`. Therefore, an instance of the shape model is searched on the pyramid level 1. If no instance of the second model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If a model was adapted with `adapt_shape_model_high_noise` the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing explicitly the lowest pyramid level as described above.

Greediness: The parameter `Greediness` determines how “greedily” the search should be carried out. If `Greediness` = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If `Greediness` = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For `Greediness` = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for `Greediness` = 0.9.

Output parameters in detail

Row, Column, Angle, and Scale: The position, rotation, and scale of the found instances of the model are returned in `Row`, `Column`, `Angle`, and `Scale`. The coordinates `Row` and `Column` are the coordinates of the origin of the shape model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the shape model with `create_scaled_shape_model`. A different origin can be set with `set_shape_model_origin`.

Note that the coordinates `Row` and `Column` do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for `find_scaled_shape_model` shows how to create this matrix and use it to display the model at the found position in the search image.

Note also that for visualizing the model at the found position, also the procedure `dev_display_shape_matching_results` can be used.

Score: The score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape models have been extended by clutter parameters using `set_shape_model_clutter`, following the above values `Score` also returns the clutter scores of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter score will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter score is 0.2 for the first instance and 0.1 for the second instance, `Score` = `[0.9, 0.8, 0.2, 0.1]` is returned. Please note that of all shape-based matching results, clutter scores are affected the most when a variation of illumination occurs.

Model: The type of the found instances of the models is returned in `Model`. The elements of `Model` are indices into the tuple `ModelIDs`, i.e., they can contain values from 0 to `|ModelIDs|` - 1. Hence, a value of 0 in an element of `Model` corresponds to an instance of the first model in `ModelIDs`.

Specifying a timeout

Using the operator `set_shape_model_param` you can specify a *'timeout'* for `find_scaled_shape_models`. If the shape models referenced by `ModelIDs` hold different values for *'timeout'*, `find_scaled_shape_models` uses the smallest one. If `find_scaled_shape_models` reaches this *'timeout'*, it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT). Depending on the scaling range specified by `ScaleMin` and `ScaleMax`, `find_scaled_shape_models` needs a significant amount of time to free cached transformations if the shape model is not pregenerated. As this transformations have to be freed after a timeout occurs, the runtime of `find_scaled_shape_models` exceeds the value of the specified *'timeout'* by this time.

MinContrast with multiple models

Please note, that the different models that are given with the parameter `ModelIDs` should have been created with the same value of `MinContrast`. If they were created with different values for `MinContrast`, `find_scaled_shape_models` will use the smallest of these values.

Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter [Transformations / 2D Transformations](#).

Parameters

- ▷ **Image** (input_object)(multichannel-)image(-array) $\leadsto$ *object* : byte / uint2
Input image in which the models should be found.
- ▷ **ModelIDs** (input_control) shape_model(-array) $\leadsto$ *handle*
Handle of the models.
- ▷ **AngleStart** (input_control) angle.rad(-array) $\leadsto$ *real*
Smallest rotation of the models.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad(-array) $\leadsto$ *real*
Extent of the rotation angles.
Default: 0.78
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
- ▷ **ScaleMin** (input_control) number(-array) $\leadsto$ *real*
Minimum scale of the models.
Default: 0.9
Suggested values: ScaleMin $\in \{0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Restriction: ScaleMin > 0
- ▷ **ScaleMax** (input_control) number(-array) $\leadsto$ *real*
Maximum scale of the models.
Default: 1.1
Suggested values: ScaleMax $\in \{1.0, 1.1, 1.2, 1.3, 1.4, 1.5\}$
Restriction: ScaleMax $\geq$ ScaleMin
- ▷ **MinScore** (input_control) real(-array) $\leadsto$ *real*
Minimum score of the instances of the models to be found.
Default: 0.5
Suggested values: MinScore $\in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control) integer(-array) $\leadsto$ *integer*
Number of instances of the models to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in \{0, 1, 2, 3, 4, 5, 10, 20\}$

- ▷ **MaxOverlap** (input_control)real(-array) $\leadsto$ *real*
Maximum overlap of the instances of the models to be found.
Default: 0.5
Suggested values: MaxOverlap $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **SubPixel** (input_control)string(-array) $\leadsto$ *string*
Subpixel accuracy if not equal to 'none'.
Default: 'least_squares'
Suggested values: SubPixel $\in$ {'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3', 'max_deformation 4', 'max_deformation 5', 'max_deformation 6'}
- ▷ **NumLevels** (input_control)integer(-array) $\leadsto$ *integer*
Number of pyramid levels used in the matching (and lowest pyramid level to use if |NumLevels| = 2).
Default: 0
List of values: NumLevels $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **Greediness** (input_control)real(-array) $\leadsto$ *real*
"Greediness" of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: Greediness $\in$ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq \text{Greediness} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **Row** (output_control)point.y-array $\leadsto$ *real*
Row coordinate of the found instances of the models.
- ▷ **Column** (output_control)point.x-array $\leadsto$ *real*
Column coordinate of the found instances of the models.
- ▷ **Angle** (output_control)angle.rad-array $\leadsto$ *real*
Rotation angle of the found instances of the models.
- ▷ **Scale** (output_control)number-array $\leadsto$ *real*
Scale of the found instances of the models.
- ▷ **Score** (output_control)real-array $\leadsto$ *real*
Score of the found instances of the models.
- ▷ **Model** (output_control)integer-array $\leadsto$ *integer*
Index of the found instances of the models.

Example

```

read_image (Image, 'pcb_focus/pcb_focus_telecentric_061')
gen_rectangle1 (ROI_0, 236, 241, 313, 321)
gen_circle (ROI_1, 281, 653, 41)
reduce_domain (Image, ROI_0, ImageReduced1)
reduce_domain (Image, ROI_1, ImageReduced2)
create_scaled_shape_model (ImageReduced1, 'auto', -0.39, 0.79, 'auto', 0.9, \
                           1.1, 'auto', 'auto', 'use_polarity', 'auto', \
                           'auto', ModelID1)
create_scaled_shape_model (ImageReduced2, 'auto', -0.39, 0.79, 'auto', 0.9, \
                           1.1, 'auto', 'auto', 'use_polarity', 'auto', \
                           'auto', ModelID2)
ModelIDs:=[ModelID1, ModelID2]
find_scaled_shape_models (Image, ModelIDs, -0.39, 0.78, 0.9, 1.1, 0.5, 1, \
                          0.5, 'least_squares', 0, 0.9, Row, Column, Angle, \
                          Scale, Score, Model)

* Display results
dev_display_shape_matching_results (ModelIDs, 'red', Row, Column, Angle, \
                                   Scale, 1, Model)

```

Result

If the parameter values are correct, the operator `find_scaled_shape_models` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

Matching

```
find_shape_model ( Image : : ModelID, AngleStart, AngleExtent,
                  MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels,
                  Greediness : Row, Column, Angle, Score )
```

Find the best matches of a shape model in an image.

The operator `find_shape_model` finds the best `NumMatches` instances of the shape model `ModelID` in the input image `Image`. The model must have been created previously by calling `create_shape_model` or `read_shape_model`.

The position and rotation of the found instances of the model is returned in `Row`, `Column`, and `Angle`. Additionally, the score of each found instance is returned in `Score`.

Input parameters in detail

Image and its domain: The domain of the image `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with `create_shape_model`. A different origin set with `set_shape_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with `set_system('border_shape_models', 'true')` for all models or with `set_shape_model_param(ModelID, 'border_shape_models', 'true')` for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.

AngleStart and AngleExtent: The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given

when the model was created with `create_shape_model`. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. `AngleStart` and `AngleExtent` are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified range.

MinScore: The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is. If the model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below `MinScore` are found.

In case that the shape model has been extended by clutter parameters with `set_shape_model_clutter` and thus `'use_clutter'` is enabled, `MinScore` expects a second value which determines what clutter score a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0. Changing this second value does not influence the runtime.

NumMatches: The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on `NumMatches`. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for `NumMatches` set to 1 might be different from the match with the highest score returned when setting `NumMatches` to 0 or > 1 .

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise `NumMatches`, and then select the match with the highest score.

In case that the shape model has been extended by clutter parameters using `set_shape_model_clutter`, `NumMatches` also considers the second value passed in `MinScore`. Matched instances will be in this case instances with a score greater than the first entry of `MinScore` and a clutter score smaller than its second entry. If the number of matched instances in the image is larger than `NumMatches`, the best `NumMatches` instances with respect to clutter scores are returned. Still, `MinScore` takes precedence over `NumMatches` and `NumMatches` must be set to 0 if all model instances fulfilling the conditions imposed by `MinScore` should be returned. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap` = 0, the found instances may not overlap at all, while for `MaxOverlap` = 1 all instances are returned.

SubPixel: The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to `'none'` (or `'false'` for backwards compatibility) the model's pose is only determined with pixel accuracy and the angle resolution that was specified with `create_shape_model`. If `SubPixel` is set to `'interpolation'` (or `'true'`) the position as well as the rotation are determined with subpixel accuracy. In this mode, the model's pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model's pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to `'interpolation'`, this mode requires additional computation time. The different modes for least-squares adjustment (`'least_squares'`, `'least_squares_high'`, and `'least_squares_very_high'`) can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually,

`SubPixel` should be set to `'interpolation'`. If least-squares adjustment is desired, `'least_squares'` should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter `SubPixel`. The deformation must be specified in pixels. This can be done by passing the optional parameter value `'max_deformation'` followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value `'max_deformation 2'` must be passed in `SubPixel` in addition to the above described mode for the subpixel extraction, i.e., for example `['least_squares', 'max_deformation 2']`. Passing the value `'max_deformation 0'` corresponds to a search without allowing deformations, i.e., the behavior is the same as if no `'max_deformation'` is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if `'max_deformation'` and `AngleExtent` are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either `'max_deformation'` or `AngleExtent` to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if `'least_squares'`, `'least_squares_high'`, or `'least_squares_very_high'` (see above) is chosen for the subpixel extraction (in comparison to `'none'` or `'interpolation'`). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

NumLevels: The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the shape model was created with `create_shape_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_shape_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_shape_model` may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_shape_model_params` and then use a slightly lower value in `find_shape_model`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of `[4,2]` for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, `SubPixel` should be set to at least `'least_squares'`. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism,

i.e., to use the so-called 'increased tolerance mode', the lowest pyramid level must be specified negatively in `NumLevels`. If, e.g., `NumLevels` is set to `[4,-2]`, the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level. This means that an instance of the shape model is searched on the pyramid level 2. If no instance of the model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If the `ModelID` was adapted with `adapt_shape_model_high_noise` the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing two values to `NumLevels` and explicitly setting the lowest pyramid level.

Greediness: The parameter `Greediness` determines how "greedily" the search should be carried out. If `Greediness` = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If `Greediness` = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For `Greediness` = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for `Greediness` = 0.9.

Output parameters in detail

Row, Column, and Angle: The position and rotation of the found instances of the model is returned in `Row`, `Column`, and `Angle`. The coordinates `Row` and `Column` are related to the position of the origin of the shape model in the search image. However, `Row` and `Column` do not exactly correspond to this position. Instead, `find_shape_model` returns slightly modified values that are optimized for creating a transformation matrix, that can be used for alignment or visualization of the model contours. (This has to do with the way HALCON transforms iconic objects, see `affine_trans_pixel`). The example below shows how to create the transformation matrix for alignment of the found matches and how to use it to display them in the search image.

By default, the model origin is the center of gravity of the domain (region) of the image that was used to create the shape model with `create_aniso_shape_model`. A different origin can be set with `set_shape_model_origin`.

Score: The score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape model has been extended by clutter parameters using `set_shape_model_clutter`, following the above values `Score` also returns the clutter score of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter score will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter score is 0.2 for the first instance and 0.1 for the second instance, `Score` = `[0.9, 0.8, 0.2, 0.1]` is returned. Please note that of all shape-based matching results, clutter scores are affected the most when a variation of illumination occurs.

Specifying a timeout

Using the operator `set_shape_model_param` you can specify a 'timeout' for `find_shape_model`. If `find_shape_model` reaches this 'timeout', it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter [Transformations / 2D Transformations](#).

Parameters

- ▷ **Image** (input_object)(multichannel-)image $\leadsto$ object : byte / uint2
Input image in which the model should be found.
- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.

- ▷ **AngleStart** (input_control) angle.rad $\leadsto$ real
Smallest rotation of the model.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad $\leadsto$ real
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
- ▷ **MinScore** (input_control) real(-array) $\leadsto$ real
Minimum score of the instances of the model to be found.
Default: 0.5
Suggested values: MinScore $\in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control) integer $\leadsto$ integer
Number of instances of the model to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in \{0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **MaxOverlap** (input_control) real $\leadsto$ real
Maximum overlap of the instances of the model to be found.
Default: 0.5
Suggested values: MaxOverlap $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **SubPixel** (input_control) string(-array) $\leadsto$ string
Subpixel accuracy if not equal to 'none'.
Default: 'least_squares'
Suggested values: SubPixel $\in \{'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation 1', 'max_deformation 2', 'max_deformation 3', 'max_deformation 4', 'max_deformation 5', 'max_deformation 6'\}$
- ▷ **NumLevels** (input_control) integer(-array) $\leadsto$ integer
Number of pyramid levels used in the matching (and lowest pyramid level to use if `|NumLevels| = 2`).
Default: 0
List of values: NumLevels $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$
- ▷ **Greediness** (input_control) real $\leadsto$ real
"Greediness" of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: Greediness $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{Greediness} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **Row** (output_control) point.y-array $\leadsto$ real
Row coordinate of the found instances of the model.
- ▷ **Column** (output_control) point.x-array $\leadsto$ real
Column coordinate of the found instances of the model.
- ▷ **Angle** (output_control) angle.rad-array $\leadsto$ real
Rotation angle of the found instances of the model.
- ▷ **Score** (output_control) real-array $\leadsto$ real
Score of the found instances of the model.

Example

```
create_shape_model (ImageReduced, 0, rad(-45), rad(180), 0, \
                  'none', 'use_polarity', 30, 10, ModelID)
get_shape_model_contours (ModelXLD, ModelID, 1)
```

```

find_shape_model (SearchImage, ModelID, rad(-45), rad(180), \
                  0.5, 1, 0.5, 'interpolation', \
                  0, 0, Row, Column, Angle, Score)
* Create transformation matrix
vector_angle_to_rigid (0, 0, 0, Row, Column, Angle, HomMat2DObject)
* Display results
dev_display_shape_matching_results (ModelID, 'red', Row, Column, Angle, \
                                   1, 1, 0)

```

Result

If the parameter values are correct, the operator `find_shape_model` returns the value 2 (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

```

find_shape_models ( Image : : ModelIDs, AngleStart, AngleExtent,
                    MinScore, NumMatches, MaxOverlap, SubPixel, NumLevels,
                    Greediness : Row, Column, Angle, Score, Model )

```

Find the best matches of multiple shape models.

The operator `find_shape_models` finds the best `NumMatches` instances of the shape models that are passed in the tuple `ModelIDs` in the input image `Image`. The models must have been created previously by calling `create_shape_model` or `read_shape_model`. In contrast to `find_shape_model`, multiple models can be searched in the same image in one call.

The position and rotation of the found instances of the model is returned in `Row`, `Column`, and `Angle`. The score of each found instance is returned in `Score`. The type of the found instances of the models is returned in `Model`. For details see respective sections below.

Characteristics of the parameter semantics

Compared to `find_shape_model`, the semantics of all input parameters have changed to some extent. All input parameters must either contain one element, in which case the parameter is used for all models, or must contain the same number of elements as `ModelIDs`, in which case each parameter element refers to the corresponding element in `ModelIDs`. (`NumLevels` may also contain either two or twice the number of elements as `ModelIDs`.) More details can be found below in the sections containing information for the respective parameters. Note that a call to `find_shape_models` with multiple values for `ModelIDs`, `NumMatches` and `MaxOverlap` has the same effect as multiple independent calls to `find_shape_model` with the respective parameters. However, a single call to `find_shape_models` is considerably more efficient.

Input parameters in detail

Image and its domain: The domain of the `Image` determines the search space for the reference point of the model, i.e., for the center of gravity of the domain (region) of the image that was used to create the shape model with `create_shape_model`. A different origin set with `set_shape_model_origin` is not taken into account. The model is searched within those points of the domain of the image, in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore` (see below). Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed with `set_system('border_shape_models', 'true')` for all models or with `set_shape_model_param(ModelID, 'border_shape_models', 'true')` for a specific model, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.

As usual, the domain of the input `Image` is used to restrict the search space for the reference point of the models `ModelIDs`. Consistent with the above semantics, the input `Image` can therefore contain a single image object or an image object tuple containing multiple image objects. If `Image` contains a single image object, its domain is used as the region of interest for all models in `ModelIDs`. If `Image` contains multiple image objects, each domain is used as the region of interest for the corresponding model in `ModelIDs`. In this case, the images have to be identical except for their domains, i.e., their pointers have to be identical (the pointers can be checked using `get_image_pointer1`). As a consequence, `Image` cannot be constructed in an arbitrary manner using `concat_obj`, but must be created from the same image using `add_channels` or equivalent calls. If this is not the case, an error message is returned.

AngleStart and AngleExtent: The parameters `AngleStart` and `AngleExtent` determine the range of rotations for which the model is searched. If necessary, the range of rotations is clipped to the range given when the model was created with `create_shape_model`. In particular, this means that the angle ranges of the model and the search must overlap.

Note that in some cases instances with a rotation that is slightly outside the specified range are found. This may happen if the specified range is smaller than the range given during the creation of the model. `AngleStart` and `AngleExtent` are checked only at the highest pyramid level. Matches that are found on the highest pyramid level are refined to the lowest pyramid level. For performance reasons, however, during the refinement it is no longer checked whether the matches are still within the specified range.

MinScore: The parameter `MinScore` determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger `MinScore` is chosen, the faster the search is. If the model can be expected never to be occluded in the images, `MinScore` may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level (see below) it might happen that instances with a score slightly below `MinScore` are found.

If a single value is passed in `MinScore`, this value is applied to found instances of all models. If, on the other hand, `MinScore` contains multiple values, the values are applied separately for the respective model. In case that the shape models have been extended by clutter parameters with `set_shape_model_clutter` and thus `'use_clutter'` is enabled, `MinScore` expects for each minimum score an additional value which determines what clutter score a potential match must at most have to be regarded as an instance of the model in the image. The runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0. Changing this second value does not influence the runtime. Note that the different shape models must have the same value for `'use_clutter'`.

If the maximum clutter is specified separately for each model, which is needed if also the minimum score is set for each model individually, `MinScore` must contain twice the number of elements as `ModelIDs`. In this case, the minimum score and the maximum clutter must be specified interleaved in `MinScore`. If, for example, two models are specified in `ModelIDs`, the minimum score is 0.9 for the first model and 0.8 for the second model, and the maximum clutter is 0.1 for the first model and 0.2 for the second model, `MinScore = [0.9, 0.1, 0.8, 0.2]` must be selected.

NumMatches: The maximum number of instances to be found can be determined with `NumMatches`. If more than `NumMatches` instances with a score greater than `MinScore` are found in the image, only the best `NumMatches` instances are returned. If fewer than `NumMatches` are found, only that number is returned,

i.e., the parameter `MinScore` takes precedence over `NumMatches`. If all model instances exceeding `MinScore` in the image should be found, `NumMatches` must be set to 0.

When tracking the matches through the image pyramid, on each level, some less promising matches are rejected based on `NumMatches`. Thus, it is possible that some matches are rejected that would have had a higher score on the lowest pyramid level. Due to this, for example, the found match for `NumMatches` set to 1 might be different from the match with the highest score returned when setting `NumMatches` to 0 or > 1.

If multiple objects with a similar score are expected, but only the one with the highest score should be returned, it might be preferable to raise `NumMatches`, and then select the match with the highest score.

In case that the shape models have been extended by clutter parameters using `set_shape_model_clutter`, `NumMatches` also considers the second value passed in `MinScore`: If more than `NumMatches` instances with a score greater than the first entry of `MinScore` and a clutter score smaller than the second entry of `MinScore` are found in the image, only the best `NumMatches` instances with respect to clutter are returned. Still, `MinScore` takes precedence over `NumMatches` and `NumMatches` must be set to 0 if all model instances fulfilling the conditions imposed by `MinScore` should be found. Please note that using clutter parameters, when tracking the matches through the image pyramid, no matches are rejected. Thus the runtime using clutter parameters will be at least as high as the runtime without clutter parameters and `NumMatches` set to 0.

If `NumMatches` contains one element, `find_shape_models` returns the best `NumMatches` instances of the model irrespective of the type of the model. If, for example, two models are passed in `ModelIDs` and `NumMatches` = 2 is selected, it can happen that two instances of the first model and no instances of the second model, one instance of the first model and one instance of the second model, or no instances of the first model and two instances of the second model are returned. If, on the other hand, `NumMatches` contains multiple values, the number of instances returned of the different models corresponds to the number specified in the respective entry in `NumMatches`. If, for example, `NumMatches` = [1, 1] is selected, one instance of the first model and one instance of the second model is returned.

MaxOverlap: If the model exhibits symmetries it may happen that multiple instances with similar positions but different rotations are found in the image. The parameter `MaxOverlap` determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than `MaxOverlap` only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If `MaxOverlap` = 0, the found instances may not overlap at all, while for `MaxOverlap` = 1 all instances are returned.

If a single value is passed in `MaxOverlap`, the overlap is computed for all found instances of the different models, irrespective of the model type, i.e., instances of the same or of different models that overlap too much are eliminated. If, on the other hand, multiple values are passed in `MaxOverlap`, the overlap is only computed for found instances of the model that have the same model type, i.e., only instances of the same model that overlap too much are eliminated. In this mode, models of different types may overlap completely.

SubPixel: The parameter `SubPixel` determines whether the instances should be extracted with subpixel accuracy. If `SubPixel` is set to 'none' (or 'false' for backwards compatibility) the model's pose is only determined with pixel accuracy and the angle resolution that was specified with `create_shape_model`. If `SubPixel` is set to 'interpolation' (or 'true') the position as well as the rotation are determined with subpixel accuracy. In this mode, the model's pose is interpolated from the score function. This mode costs almost no computation time and achieves an accuracy that is high enough for most applications. In some applications, however, the accuracy requirements are extremely high. In these cases, the model's pose can be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In contrast to 'interpolation', this mode requires additional computation time. The different modes for least-squares adjustment ('least_squares', 'least_squares_high', and 'least_squares_very_high') can be used to determine the accuracy with which the minimum distance is being searched. The higher the accuracy is chosen, the longer the subpixel extraction will take, however. Usually, `SubPixel` should be set to 'interpolation'. If least-squares adjustment is desired, 'least_squares' should be chosen because this results in the best trade-off between runtime and accuracy.

Objects that are slightly deformed with respect to the model, in some cases cannot be found or are found but only with a low accuracy. For such objects it is possible to additionally pass a maximal allowable object deformation in the parameter `SubPixel`. The deformation must be specified in pixels. This can be done by passing the optional parameter value 'max_deformation' followed by an integer value between 0 and 32 (in the same string), which specifies the maximum deformation. For example, if the shape of the object may be deformed by up to 2 pixels with respect to the shape that is stored in the model, the value 'max_deformation 2' must be passed in `SubPixel` in addition to the above described mode for the subpixel extraction, i.e.,

for example `['least_squares', 'max_deformation 2']`. Passing the value `'max_deformation 0'` corresponds to a search without allowing deformations, i.e., the behavior is the same as if no `'max_deformation'` is passed. Note that higher values for the maximum deformation often result in an increased runtime. Furthermore, the higher the deformation value is chosen, the higher is the risk of finding wrong model instances. Both problems mainly arise when searching for small objects or for objects with fine structures. This is because such kinds of objects for higher deformations lose their characteristic shape, which is important for a robust search. Also note that for higher deformations the accuracy of partially occluded objects might decrease if clutter is present close to the object. Consequently, the maximum deformation should be chosen as small as possible and only as high as necessary. Approximately rotationally symmetric objects may not be found if `'max_deformation'` and `AngleExtent` are both set to a value greater than 0. In that case, ambiguities may occur that cannot be resolved, and the match is rejected as false. If this happens, try to set either `'max_deformation'` or `AngleExtent` to 0, or adjust the model such that symmetries are reduced. When specifying a deformation higher than 0 the computation of the score depends on the chosen value for the subpixel extraction. In most cases, the score of a match changes if `'least_squares'`, `'least_squares_high'`, or `'least_squares_very_high'` (see above) is chosen for the subpixel extraction (in comparison to `'none'` or `'interpolation'`). Furthermore, if one of the least-squares adjustments is selected the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found. To get a meaningful score value and to avoid erroneous matches, we recommend to always combine the allowance of a deformation with a least-squares adjustment.

If the subpixel extraction and/or the maximum object deformation is specified separately for each model, for each model passed in `ModelIDs` exactly one value for the subpixel extraction must be passed in `SubPixel`. After each value for the subpixel extraction optionally a second value can be passed, which describes the maximum object deformation of the corresponding mode. If for a certain model no value for the maximum object deformation is passed, the model is searched without taking deformations into account. For example, if two models are passed in `ModelIDs` and for the first model the subpixel extraction is set to `'interpolation'` and no object deformations are allowed and for the second model the subpixel extraction is set to `'least_squares'` and a maximum object deformation of 3 pixels is allowed, then the tuple `['interpolation', 'least_squares', 'max_deformation 3']` must be passed in `SubPixel`. Alternatively, the equivalent tuple `['interpolation', 'max_deformation 0', 'least_squares', 'max_deformation 3']` may be passed.

NumLevels: The number of pyramid levels used during the search is determined with `NumLevels`. If necessary, the number of levels is clipped to the range given when the shape model was created with `create_shape_model`. If `NumLevels` is set to 0, the number of pyramid levels specified in `create_shape_model` is used.

In certain cases, the number of pyramid levels that was determined automatically with, for example, `create_shape_model` may be too high. The consequence may be that some matches that may have a high final score are rejected on the highest pyramid level and thus are not found. Instead of setting `MinScore` to a very low value to find all matches, it may be better to query the value of `NumLevels` with `get_shape_model_params` and then use a slightly lower value in `find_shape_models`. This approach is often better regarding the speed and robustness of the matching.

Optionally, `NumLevels` can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of `[4,2]` for `NumLevels` means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. It should be noted, however, that in general the accuracy of the extracted pose parameters is lower in this mode than in the normal mode, in which the matches are tracked to the lowest pyramid level. Hence, if a high accuracy is desired, `SubPixel` should be set to at least `'least_squares'`. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

If the lowest pyramid level is specified separately for each model, `NumLevels` must contain twice the number of elements as `ModelIDs`. In this case, the number of pyramid levels and the lowest pyramid level must be specified interleaved in `NumLevels`. If, for example, two models are specified in `ModelIDs`, the number of pyramid levels is 5 for the first model and 4 for the second model, and the lowest pyramid level is 2 for the first model and 1 for the second model, `NumLevels = [5, 2, 4, 1]` must be selected. If exactly two models are specified in `ModelIDs`, a special case occurs. If in this case the lowest pyramid level is to be specified, the number of pyramid levels and the lowest pyramid level must be specified explicitly for both models, even if they are identical, because specifying two values in `NumLevels` is interpreted as the explicit

specification of the number of pyramid levels for the two models.

In input images of poor quality, i.e., in images that are, e.g., defocused, deformed, or noisy, often no instances of the shape model can be found on the lowest pyramid level. The reason for this behavior is the missing or deformed edge information which is a result of the poor image quality. Nevertheless, the edge information may be sufficient on higher pyramid levels. But keep in mind the above mentioned restrictions on accuracy and robustness if instances that were found on higher pyramid levels are used. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. This pyramid level may vary from image to image. To facilitate the matching on images of poor quality, the lowest pyramid level on which at least one instance of the model can be found can be determined automatically during the matching. To activate this mechanism, i.e., to use the so-called 'increased tolerance mode', the lowest pyramid level must be specified negatively in `NumLevels`. If, e.g., `NumLevels` is set to `[5,2,4,-1]`, the lowest pyramid level for the first model is set to 2. If no instance of the first model can be found on this pyramid level, no result will be returned for this model. For the second shape model, the lowest pyramid level is set to `-1`. Therefore, an instance of the shape model is searched on the pyramid level 1. If no instance of the second model can be found on this pyramid level, the lowest pyramid level is determined on which at least one instance of the model can be found. The instances of this pyramid level will then be returned.

If a model was adapted with `adapt_shape_model_high_noise` the estimated lowest pyramid level will be used by default. However, the user can override the estimated lowest pyramid level by providing explicitly the lowest pyramid level as described above.

Greediness: The parameter `Greediness` determines how “greedily” the search should be carried out. If `Greediness` = 0, a safe search heuristic is used, which always finds the model if it is visible in the image and the other parameters are set appropriately. However, the search will be relatively time consuming in this case. If `Greediness` = 1, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For `Greediness` = 1, the maximum search speed is achieved. In almost all cases, the shape model will always be found for `Greediness` = 0.9.

Output parameters in detail

Row, Column, and Angle: The position and rotation of the found instances of the model is returned in `Row`, `Column`, and `Angle`. The coordinates `Row` and `Column` are the coordinates of the origin of the shape model in the search image. By default, the origin is the center of gravity of the domain (region) of the image that was used to create the shape model with `create_shape_model`. A different origin can be set with `set_shape_model_origin`.

Note that the coordinates `Row` and `Column` do not exactly correspond to the position of the model in the search image. Thus, you cannot directly use them. Instead, the values are optimized for creating the transformation matrix with which you can use the results of the matching for various tasks, e.g., to align ROIs for other processing steps. The example given for `find_shape_model` shows how to create this matrix and use it to display the model at the found position in the search image.

Note also that for visualizing the model at the found position, also the procedure `dev_display_shape_matching_results` can be used.

Score: The score of each found instance is returned in `Score`. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

In case that the shape models have been extended by clutter parameters using `set_shape_model_clutter`, following the above values `Score` also returns the clutter scores of each found instance. If, for example, half of the clutter region is filled by clutter edges, the clutter score will equal 0.5. If, e.g., two instances are found, the score is 0.9 for the first instance and 0.8 for the second instance, and the clutter score is 0.2 for the first instance and 0.1 for the second instance, `Score` = `[0.9, 0.8, 0.2, 0.1]` is returned. Please note that of all shape-based matching results, clutter scores are affected the most when a variation of illumination occurs.

Model: The type of the found instances of the models is returned in `Model`. The elements of `Model` are indices into the tuple `ModelIDs`, i.e., they can contain values from 0 to `|ModelIDs| - 1`. Hence, a value of 0 in an element of `Model` corresponds to an instance of the first model in `ModelIDs`.

Specifying a timeout

Using the operator `set_shape_model_param` you can specify a 'timeout' for `find_shape_models`. If the shape models referenced by `ModelIDs` hold different values for 'timeout', `find_shape_models` uses the

smallest one. If `find_shape_models` reaches this *'timeout'*, it terminates without results and returns the error code 9400 (H_ERR_TIMEOUT).

MinContrast with multiple models

Please note, that the different models that are given with the parameter `ModelIDs` should have been created with the same value of `MinContrast`. If they were created with different values for `MinContrast`, `find_shape_models` will use the smallest of these values.

Visualization of the results

To display the results found by shape-based matching, we highly recommend the usage of the procedure `dev_display_shape_matching_results`.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter [Transformations / 2D Transformations](#).

Parameters

- ▷ **Image** (input_object)(multichannel-)image(-array) $\leadsto$ *object* : byte / uint2
Input image in which the models should be found.
- ▷ **ModelIDs** (input_control) shape_model(-array) $\leadsto$ *handle*
Handle of the models.
- ▷ **AngleStart** (input_control) angle.rad(-array) $\leadsto$ *real*
Smallest rotation of the models.
Default: -0.39
Suggested values: AngleStart $\in \{-3.14, -1.57, -0.79, -0.39, -0.20, 0.0\}$
- ▷ **AngleExtent** (input_control) angle.rad(-array) $\leadsto$ *real*
Extent of the rotation angles.
Default: 0.79
Suggested values: AngleExtent $\in \{6.29, 3.14, 1.57, 0.79, 0.39, 0.0\}$
Restriction: AngleExtent ≥ 0
- ▷ **MinScore** (input_control) real(-array) $\leadsto$ *real*
Minimum score of the instances of the models to be found.
Default: 0.5
Suggested values: MinScore $\in \{0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MinScore} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **NumMatches** (input_control) integer(-array) $\leadsto$ *integer*
Number of instances of the models to be found (or 0 for all matches).
Default: 1
Suggested values: NumMatches $\in \{0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **MaxOverlap** (input_control) real(-array) $\leadsto$ *real*
Maximum overlap of the instances of the models to be found.
Default: 0.5
Suggested values: MaxOverlap $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{MaxOverlap} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **SubPixel** (input_control) string(-array) $\leadsto$ *string*
Subpixel accuracy if not equal to *'none'*.
Default: 'least_squares'
Suggested values: SubPixel $\in \{'none', 'interpolation', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'max_deformation_1', 'max_deformation_2', 'max_deformation_3', 'max_deformation_4', 'max_deformation_5', 'max_deformation_6'\}$
- ▷ **NumLevels** (input_control) integer(-array) $\leadsto$ *integer*
Number of pyramid levels used in the matching (and lowest pyramid level to use if `|NumLevels| = 2`).
Default: 0
List of values: NumLevels $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$

- ▷ **Greediness** (input_control)real(-array) $\leadsto$ real
 “Greediness” of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: Greediness $\in \{0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0\}$
Value range: $0 \leq \text{Greediness} \leq 1$
Minimum increment: 0.01
Recommended increment: 0.05
- ▷ **Row** (output_control)point.y-array $\leadsto$ real
 Row coordinate of the found instances of the models.
- ▷ **Column** (output_control)point.x-array $\leadsto$ real
 Column coordinate of the found instances of the models.
- ▷ **Angle** (output_control)angle.rad-array $\leadsto$ real
 Rotation angle of the found instances of the models.
- ▷ **Score** (output_control)real-array $\leadsto$ real
 Score of the found instances of the models.
- ▷ **Model** (output_control)integer-array $\leadsto$ integer
 Index of the found instances of the models.

Example

```
read_image (Image, 'pcb_focus/pcb_focus_telecentric_061')
gen_rectangle1 (ROI_0, 236, 241, 313, 321)
gen_circle (ROI_1, 281, 653, 41)
reduce_domain (Image, ROI_0, ImageReduced1)
reduce_domain (Image, ROI_1, ImageReduced2)

create_shape_model (ImageReduced1, 0, rad(-45), rad(180), 0, \
                    'none', 'use_polarity', 30, 10, ModelID1)
create_shape_model (ImageReduced2, 0, rad(-45), rad(180), 0, \
                    'none', 'use_polarity', 30, 10, ModelID2)
ModelIDs:=[ModelID1, ModelID2]
find_shape_models (Image, ModelIDs, rad(-45), rad(90), 0.7, [1,1], 0.5, \
                  'least_squares', 0, 1, Row, Column, Angle, Score, Model)
* Display results
dev_display_shape_matching_results (ModelIDs, 'red', Row, Column, Angle, \
                                   1, 1, Model)
```

Result

If the parameter values are correct, the operator `find_shape_models` returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

`add_channels`, `create_shape_model`, `read_shape_model`, `set_shape_model_origin`,
`set_shape_model_param`, `set_shape_model_clutter`

Possible Successors

`clear_shape_model`

Alternatives

`find_generic_shape_model`

`set_system`, `get_system`

Module

Matching

```
get_generic_shape_model_object ( : Object : ModelID,
                                GenParamName : )
```

Get iconic objects of the shape model.

The operator `get_generic_shape_model_object` reads out objects of the shape model `ModelID` and returns them in `Object`.

`GenParamName` specifies which iconic object will be returned. The following values are possible:

'clutter_region': The clutter region of the shape model.

'contours': Representation of the shape model `ModelID` for the bottom-most pyramid level as XLD contours. Thereby the contour is translated so that the origin of the model with the coordinates `'origin_row'` and `'origin_column'` (see `set_generic_shape_model_param`) is located at the origin of the pixel centered HALCON standard coordinate system (see [Transformations / 2D Transformations](#)). The contours can be used, for example, to visualize the found instances of the model in an image.

Parameters

- ▷ **Object** (output_object) (multichannel-)object(-array) $\leadsto$ *object*
Iconic object to be returned.
- ▷ **ModelID** (input_control) shape_model $\leadsto$ *handle*
Handle of the shape model.
- ▷ **GenParamName** (input_control) string-array $\leadsto$ *string*
Parameter names.
Default: `'clutter_region'`
List of values: `GenParamName` $\in$ `{'clutter_region', 'contours'}`

Result

If the parameters are valid, the operator `get_generic_shape_model_object` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_generic_shape_model`, `set_generic_shape_model_object`,
`train_generic_shape_model`

Module

Matching

```
get_generic_shape_model_param ( : : ModelID,
                                GenParamName : GenParamValue )
```

Return the parameters of a shape model.

The operator `get_generic_shape_model_param` returns the parameters values `GenParamValue` of `GenParamName` for the shape model `ModelID`.

For an explanation of the settable `GenParamValue`, see `set_generic_shape_model_param`. Additional parameters whose value can only be retrieved:

- **'needs_training'**:
States, whether the model must be trained using `train_generic_shape_model` before it can be used by `find_generic_shape_model` (`'true'`) or not (`'false'`).
- **'scale_type'**:
A string which describes the type of scaling of the shape model.

The operator `get_generic_shape_model_param` returns the value as it is used by the shape model. As certain parameters may be modified after calling `train_generic_shape_model`, their value can differ from the set value. This applies particularly to parameters whose value is to be determined automatically, e.g., with values set to `'auto'`. The (unmodified) set value of a `GenParamName` can be retrieved by adding the suffix `'_param'` to its name.

Example: After calling `train_generic_shape_model`, `'num_levels'` returns the estimated value and `'num_levels_param'` returns the set value, e.g., its value set by default or the one set by the user.

Parameters

- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the shape model.
- ▷ **GenParamName** (input_control) attribute.name-array $\leadsto$ string
Parameter name.
Default: `'min_score'`
List of values: `GenParamName` $\in$ `{'angle_end', 'angle_start', 'angle_step', 'border_shape_models', 'clutter_border_mode', 'clutter_contrast', 'clutter_hom_mat_2d', 'contrast_high', 'contrast_low', 'greediness', 'iso_scale_max', 'iso_scale_min', 'iso_scale_step', 'max_clutter', 'max_deformation', 'max_overlap', 'max_overlap_global_enable', 'metric', 'min_contrast', 'min_score', 'min_size', 'model_cache', 'model_identifier', 'needs_training', 'num_levels', 'num_matches', 'optimization', 'origin_column', 'origin_row', 'prepare_contours_for_visualization', 'prepare_clutter_region_for_visualization', 'pyramid_level_highest', 'pyramid_level_lowest', 'pyramid_level_robust_tracking', 'restrict_iso_scale_max', 'restrict_iso_scale_min', 'restrict_scale_column_max', 'restrict_scale_column_min', 'restrict_scale_row_max', 'restrict_scale_row_min', 'scale_column_max', 'scale_column_min', 'scale_column_step', 'scale_row_max', 'scale_row_min', 'scale_row_step', 'scale_type', 'strict_boundaries', 'subpixel', 'time_measurement', 'timeout', 'use_clutter'}`
- ▷ **GenParamValue** (output_control) attribute.value-array $\leadsto$ real / integer / string
Parameter value.

Result

If the parameters are valid, the operator `get_generic_shape_model_param` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ModelID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`train_generic_shape_model`

Module

Matching

```
get_generic_shape_model_result ( : : MatchResultID,
                                MatchSelector, GenParamName : GenParamValue )
```

Get alphanumerical values from a shape matching result.

`get_generic_shape_model_result` returns alphanumerical results of shape-based matching in `GenParamValue`. The matches are contained in `MatchResultID` and sorted by descending score.

The parameter `MatchSelector` is used to select from which matches the result values shall be returned. The sorting remains according to their score. Hence, it is independent of the order of the selection criteria passed in `MatchSelector`. Furthermore, a matching result is only returned once even if it meets more than one selection criterion.

`MatchSelector` processes selection criteria of the following types or combinations of them:

- `'all'`:
All matching results are selected.
- `'best'`:
The match with the highest score is selected.
- Result index:
By setting `MatchSelector` to an integer, the index of the match in `MatchResultID` is determined.
Value range: 0 to n-1 (with n as the total number of results).
If the index is outside the valid range, an exception is raised.
- Shape model identifier:
All matches found with a specific shape model are selected. For this you can pass the respective model identifier `'model_identifier'` as a string to `MatchSelector`.
- Shape model handle:
All matches found with a specific shape model are selected. For this you can pass the respective shape model handle to `MatchSelector`.

If `MatchSelector` is no valid selection criterion, an exception is raised.

`GenParamName` specifies which alphanumerical result value will be returned. The following values are possible:

- `'num_match_result'`:
Number of matches. The accumulated number of matches is returned in case multiple selections are made in `MatchSelector`.
- `'model_identifier'`:
String identifying the model the match was found with.
- `'score'`:
Score of the found match. It is a number between 0 and 1 and an approximate measure of how good the model is found in the image. For further information on scores, see "Solution Guide II-B – Matching", Chapter 'General Topics', section 'About the Score'.
- `'angle'`:
Rotation angle of the found match.
Value range: $-3.14 \leq 'angle' \leq 3.14$ ($=\pi$).
- `'row'`:
Row coordinate of the found match in the search image. The coordinate relates to the origin of the shape model.
- `'column'`:
Column coordinate of the found match in the search image. The coordinate relates to the origin of the shape model.
- `'scale_row'`:
Scale of the found match in row direction.
- `'scale_column'`:
Scale of the found match in column direction.
- `'hom_mat_2d'`:
Homographic transformation matrix to transform the contours of the shape model from its origin to the found location in the search image. Position, rotation, and scaling in row and column direction are taken into account. For more information on transformations with homographic matrices see `affine_trans_point_2d`.

- **'clutter_score'**:
Clutter score of the found match. It is a number between 0 and 1 and an approximate measure of how much clutter edges are present in the clutter region.
- **'clutter_hom_mat_2d'**:
Homographic transformation matrix to transform the clutter region of the shape model from its origin to the found location in the search image. Position, rotation, and scaling in row and column direction are taken into account.
- **'match'**:
Dictionary containing the coordinate **'row'**, **'column'**, the rotation angle **'angle'**, the scale **'scale_row'**, **'scale_column'**, the score **'score'**, and the homographic transformation **'hom_mat_2d'** of the found match. Additionally, the two clutter-specific results **'clutter_score'** and **'clutter_hom_mat_2d'** are contained in the dictionary if clutter has been trained and used (see [set_generic_shape_model_object](#) with **'clutter_region'**).
- **'time_measurement'**:
A dictionary containing the different time measurements that were conducted during the search. Note that their sum is less than the total time spent on the operator call. The dictionary contains time measurements for the four main steps of the search pipeline **'pipeline'**:
 - **'pyramid'**: Time spent constructing the image pyramid.
 - **'top_level'**: Time spent searching for candidates on highest pyramid level.
 - **'tracking'**: Time spent tracking candidates from the highest pyramid level to the lowest.
 - **'subpixel_refinement'**: Time spent conducting the refinement at the end of the search.

Restriction: [MatchSelector](#) must be set to **'all'**.

Note that for values regarding the location of the matches coordinates are given as edge centered coordinates. For more information on edge centered coordinates see the chapter [Transformations / 2D Transformations](#).

Parameters

- ▷ **MatchResultID** (input_control) generic_shape_model_result $\leadsto$ handle
Handle of the shape model matches.
- ▷ **MatchSelector** (input_control) string-array $\leadsto$ string / integer
Selector for the matching results to be queried.
Default: **'all'**
List of values: MatchSelector $\in$ {**'all'**, **'best'**}
- ▷ **GenParamName** (input_control) attribute.name $\leadsto$ string
Name of the queried result parameter.
Default: **'score'**
List of values: GenParamName $\in$ {**'num_match_result'**, **'model_identifier'**, **'score'**, **'angle'**, **'row'**, **'column'**, **'scale_row'**, **'scale_column'**, **'hom_mat_2d'**, **'clutter_score'**, **'clutter_hom_mat_2d'**, **'match'**, **'time_measurement'**}
- ▷ **GenParamValue** (output_control) attribute.value-array $\leadsto$ real / integer / string
Value of the queried result parameter.

Result

If the parameters are valid, the operator `get_generic_shape_model_result` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

[find_generic_shape_model](#)

Module

Matching

```
get_generic_shape_model_result_object (
    : Objects : MatchResultID, MatchSelector, GenParamName : )
```

Get objects from a shape matching result.

`get_generic_shape_model_result_object` returns iconic results of shape-based matching in `Objects`. The results are contained in `MatchResultID`.

The parameter `MatchSelector` is used to select from which matches the result values shall be returned. For more information and the list of supported values for `MatchSelector` see `get_generic_shape_model_result`.

`GenParamName` specifies which object result value will be returned. The following values are possible:

'contours': Model contours transformed according to the matching result.

'clutter_region': Region where no clutter should occur.

Parameters

- ▷ **Objects** (output_object) (multichannel-)object(-array) $\leadsto$ *object*
Objects of the queried result.
- ▷ **MatchResultID** (input_control) generic_shape_model_result $\leadsto$ *handle*
Handle of the shape model matches.
- ▷ **MatchSelector** (input_control) string-array $\leadsto$ *string / integer*
Selector for the matching results to be queried.
Default: 'all'
List of values: MatchSelector $\in$ {'all', 'best'}
- ▷ **GenParamName** (input_control) string $\leadsto$ *string*
Name of the queried result object.
Default: 'contours'
List of values: GenParamName $\in$ {'contours', 'clutter_region'}

Result

If the parameters are valid, the operator `get_generic_shape_model_result_object` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`find_generic_shape_model`

Module

Matching

```
get_shape_model_clutter ( : ClutterRegion : ModelID,
    GenParamName : GenParamValue, HomMat2D, ClutterContrast )
```

Get the clutter parameters of a shape model.

The operator `get_shape_model_clutter` can be used to inspect clutter parameters of the shape model `ModelID`, which have been set previously using `set_shape_model_clutter`. Also, the value of 'use_clutter', which can be set using `set_shape_model_param`, can be queried by setting `GenParamName` to 'use_clutter'. For a description of the parameters, please see `set_shape_model_clutter` and `set_shape_model_param`.

Parameters

- ▷ **ClutterRegion** (output_object)region $\leadsto$ object
Region where no clutter should occur.
- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.
- ▷ **GenParamName** (input_control)attribute.name(-array) $\leadsto$ string
Parameter names.
Default: 'use_clutter'
List of values: GenParamName $\in$ {'use_clutter', 'clutter_border_mode'}
- ▷ **GenParamValue** (output_control)attribute.name(-array) $\leadsto$ string / real / integer
Parameter values.
- ▷ **HomMat2D** (output_control)hom_mat2d $\leadsto$ real
Transformation matrix.
- ▷ **ClutterContrast** (output_control) number $\leadsto$ integer
Minimum contrast of clutter in the search images.

Result

If the parameters are valid, the operator `get_shape_model_clutter` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

get_shape_model_contours (: ModelContours : ModelID, Level :)

Return the contour representation of a shape model.

The operator `get_shape_model_contours` returns a representation of the shape model `ModelID` as XLD contours in `ModelContours`. The parameter `Level` determines for which pyramid level of the model the contour representation should be returned. The contours can be used, for example, to visualize the found instances of the model in an image. It should be noted that the position of `ModelContours` is normalized such that the reference point of the model (see `set_shape_model_origin`) lies at the pixel position (0,0). Hence, the contours simply need to be translated to the found position in the image (and possibly rotated and scaled around this point).

Parameters

- ▷ **ModelContours** (output_object) xld_cont-array $\leadsto$ object
Contour representation of the shape model.
- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.

- ▷ **Level** (input_control) integer $\leadsto$ integer
Pyramid level for which the contour representation should be returned.
Default: 1
Suggested values: Level $\in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$
Restriction: Level ≥ 1

Result

If the handle of the model is valid, the operator `get_shape_model_contours` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

get_shape_model_origin (: : ModelID : Row, Column)

Return the origin (reference point) of a shape model.

The operator `get_shape_model_origin` returns the origin (reference point) of the shape model `ModelID`. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the shape model with `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`. Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

Parameters

- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.
- ▷ **Row** (output_control) point.y $\leadsto$ real
Row coordinate of the origin of the shape model.
- ▷ **Column** (output_control) point.x $\leadsto$ real
Column coordinate of the origin of the shape model.

Result

If the handle of the model is valid, the operator `get_shape_model_origin` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
get_shape_model_params ( : : ModelID : NumLevels, AngleStart,
    AngleExtent, AngleStep, ScaleMin, ScaleMax, ScaleStep, Metric,
    MinContrast )
```

Return the parameters of a shape model.

The operator `get_shape_model_params` returns the parameters of the shape model `ModelID` that were used to create it using `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`. In particular, this output can be used to check the parameters `NumLevels`, `AngleStep`, `ScaleStep`, and `MinContrast` if they were determined automatically during the model creation with `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`.

If the `ModelID` was adapted with `adapt_shape_model_high_noise`, `NumLevels` contains two values: the highest pyramid level and the estimated lowest pyramid level.

If the shape model was created using `create_shape_model` or `create_scaled_shape_model` a single value is returned in `ScaleMin`, `ScaleMax`, and `ScaleStep`. This parameters corresponds to the isotropic scaling parameters of the shape model. If the shape model was created using `create_aniso_shape_model` two values each are returned in the above three parameters. Here, the first value of the respective parameter refers to the scaling in the row direction, while the second value refers to the scaling in the column direction.

Note that the parameters `Optimization` and `Contrast` that also can be determined automatically during the model creation cannot be queried by using `get_shape_model_params`. If their value is of interest `determine_shape_model_params` should be used instead.

Parameters

- ▷ **ModelID** (input_control) shape_model $\rightsquigarrow$ *handle*
Handle of the model.
- ▷ **NumLevels** (output_control) integer(-array) $\rightsquigarrow$ *integer*
Number of pyramid levels.
- ▷ **AngleStart** (output_control) angle.rad $\rightsquigarrow$ *real*
Smallest rotation of the pattern.
- ▷ **AngleExtent** (output_control) angle.rad $\rightsquigarrow$ *real*
Extent of the rotation angles.
Assertion: AngleExtent $\geq$ 0
- ▷ **AngleStep** (output_control) angle.rad $\rightsquigarrow$ *real*
Step length of the angles (resolution).
Assertion: AngleStep $\geq$ 0 && AngleStep $\leq$ pi / 2
- ▷ **ScaleMin** (output_control) number(-array) $\rightsquigarrow$ *real*
Minimum scale of the pattern.
Assertion: ScaleMin $>$ 0
- ▷ **ScaleMax** (output_control) number(-array) $\rightsquigarrow$ *real*
Maximum scale of the pattern.
Assertion: ScaleMax $\geq$ ScaleMin
- ▷ **ScaleStep** (output_control) number(-array) $\rightsquigarrow$ *real*
Scale step length (resolution).
Assertion: ScaleStep $\geq$ 0
- ▷ **Metric** (output_control) string $\rightsquigarrow$ *string*
Match metric.

▷ **MinContrast** (output_control)number $\leadsto$ integer
Minimum contrast of the objects in the search images.

Result

If the handle of the model is valid, the operator `get_shape_model_params` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Matching

```
inspect_shape_model ( Image : ModelImages,
                      ModelRegions : NumLevels, Contrast : )
```

Create the representation of a shape model.

`inspect_shape_model` creates a representation of a shape model. The operator is particularly useful in order to determine the parameters `NumLevels` and `Contrast`, which are used in `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model`, quickly and conveniently. The representation of the model is created on multiple image pyramid levels, where the number of levels is determined by `NumLevels`. In contrast to `create_shape_model`, `create_scaled_shape_model`, and `create_aniso_shape_model`, the model is only created for the rotation and scale of the object in the input image, i.e., 0° and 1. As output, `inspect_shape_model` creates an image object `ModelImages` containing the images of the individual levels of the image pyramid as well as a region in `ModelRegions` for each pyramid level that represents the model at the respective pyramid level. The individual objects can be accessed with `select_objj`. If the input image `Image` has one channel the representation of the model is created with the method that is used in `create_shape_model`, `create_scaled_shape_model` or `create_aniso_shape_model` for the metrics `'use_polarity'`, `'ignore_global_polarity'`, and `'ignore_local_polarity'`. If the input image has more than one channel the representation is created with the method that is used for the metric `'ignore_color_polarity'`. As described for `create_shape_model`, `create_scaled_shape_model`, and `create_aniso_shape_model`, the number of pyramid levels should be chosen as large as possible, while taking into account that the model must be recognizable on the highest pyramid level and must have enough model points. The parameter `Contrast` should be chosen such that only the significant features of the template object are used for the model. `Contrast` can also contain a tuple with two values. In this case, the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. Here, the first element of the tuple determines the lower threshold, while the second element determines the upper threshold. For more information about the hysteresis threshold method, see `hysteresis_threshold`. Optionally, `Contrast` can contain a third value as the last element of the tuple. This value determines a threshold for the selection of significant model components based on the size of the components, i.e., components that have fewer points than the minimum size thus specified are suppressed. As the minimum size is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. If small model components should be suppressed, but hysteresis thresholding should not be performed, nevertheless three values must be specified in `Contrast`. In this case, the first two values

can simply be set to identical values. In its typical use, `inspect_shape_model` is called interactively multiple times with different parameters for `NumLevels` and `Contrast`, until a satisfactory model is obtained. After this, `create_shape_model`, `create_scaled_shape_model`, or `create_aniso_shape_model` are called with the parameters thus obtained.

Parameters

- ▷ **Image** (input_object)(multichannel-)image $\leadsto$ object : byte / uint2
Input image.
- ▷ **ModelImages** (output_object)(multichannel-)image-array $\leadsto$ object : byte / uint2
Image pyramid of the input image
- ▷ **ModelRegions** (output_object)region-array $\leadsto$ object
Model region pyramid
- ▷ **NumLevels** (input_control) integer $\leadsto$ integer
Number of pyramid levels.
Default: 4
List of values: NumLevels $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
- ▷ **Contrast** (input_control) number(-array) $\leadsto$ integer
Threshold or hysteresis thresholds for the contrast of the object in the image and optionally minimum size of the object parts.
Default: 30
Suggested values: Contrast $\in$ {10, 20, 30, 40, 60, 80, 100, 120, 140, 160}

Result

If the parameters are valid, the operator `inspect_shape_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`set_generic_shape_model_param`

Module

Foundation

read_shape_model (: : FileName : ModelID)

Read a shape model from a file.

The operator `read_shape_model` reads a shape model, which has been written with `write_shape_model`, from the file `FileName`. The default HALCON file extension for the shape model is 'shm'.

Parameters

- ▷ **FileName** (input_control)filename.read $\leadsto$ string
File name.
File extension: .shm
- ▷ **ModelID** (output_control) shape_model $\leadsto$ handle
Handle of the model.

Result

If the file name is valid, the operator `read_shape_model` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

[find_generic_shape_model](#)

Module

Matching

serialize_shape_model (: : ModelID : SerializedItemHandle)

Serialize a shape model.

`serialize_shape_model` serializes the data of a shape model (see [fwrite_serialized_item](#) for an introduction of the basic principle of serialization). The same data that is written in a file by [write_shape_model](#) is converted to a serialized item. The shape model is defined by the handle `ModelID`. The serialized shape model is returned by the handle `SerializedItemHandle` and can be deserialized by [deserialize_shape_model](#).

Parameters

- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.
- ▷ **SerializedItemHandle** (output_control) serialized_item $\leadsto$ handle
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_shape_model` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_generic_shape_model_object (Object : : ModelID,
GenParamName :)

Set iconic objects to the shape model.

The operator `set_generic_shape_model_object` sets parameters of the shape model `ModelID` based on the given `Object`.

The parameter `GenParamName` determines for which type of setting the object is used. The following values are supported:

- *'high_noise_sample'*: Estimate and adapt the shape model parameters to cope better with high noise images. The parameter estimation is done based on the sample search image [Object](#). As a consequence the domain of [Object](#) should contain the model and surrounding background showing noise that is typical for search images.

The operator modifies the following parameters:

- *'pyramid_level_lowest'*
- *'clutter_region'*: Set the clutter region for the shape model. If *'clutter_region'* is set, the value of *'use_clutter'* is automatically set to *'true'*.
Note that the *'clutter_region'* must not intersect with the final model contours that are generated by [train_generic_shape_model](#).
If the clutter region would need negative coordinates (e.g., clutter regions for XLD models which have the center in the image origin), the transformation has to be provided. To do so, use [set_generic_shape_model_param](#) with *'clutter_hom_mat_2d'*.

Parameters

- ▷ **Object** (input_object)(multichannel-)object(-array) $\leadsto$ *object*
Iconic object to be set.
- ▷ **ModelID** (input_control) shape_model $\leadsto$ *handle*
Handle of the shape model.
- ▷ **GenParamName** (input_control) string-array $\leadsto$ *string*
Parameter name.
Default: *'high_noise_sample'*
List of values: `GenParamName` $\in$ {*'clutter_region'*, *'high_noise_sample'*}

Result

If the parameters are valid, the operator `set_generic_shape_model_object` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ModelID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

```
set_generic_shape_model_param ( : : ModelID, GenParamName,
    GenParamValue : )
```

Set selected parameters of the shape model.

The operator `set_generic_shape_model_param` sets the parameters [GenParamName](#) of the shape model [ModelID](#) to the values given in [GenParamValue](#).

Various aspects of the matching process can be controlled by the parameters that can be selected by [GenParamName](#). In the descriptions below they are grouped into the following categories (where the category represents the main purpose but not necessarily the only purpose of the parameter listed within):

Modifying the Model

Finding Model Instances

1. Modify the Instance
2. Sort out Found Matches
3. Gray Value Treatment
4. Refinement
5. Image Pyramid
6. Clutter
7. Regarding the Output

Computational Resources during a Search

In the following we list the settable parameters for the different categories and specify cases in which parameter values are modified automatically.

Modifying the Model

In this paragraph we list and explain parameters modifying the model `ModelID` itself. Changing a corresponding value makes it necessary to train the adjusted model before the matching (see `train_generic_shape_model`). The supported parameters `GenParamName` are:

Contrast The contrast is a measure for local gray value differences that are used to distinguish the object from the background or different parts of the object from each other. For the model only those pixels are selected which show the asked contrast, i.e., gray value difference to neighboring pixels. This asked contrast can be a simple threshold or a hysteresis threshold, depending on the values set for `'contrast_low'` and `'contrast_high'`:

- Simple threshold:
 - Both are set to the same value which is not `'auto'`.
 - One of the parameters is set to `'auto'` while the other one is set to an other value.
- Hysteresis threshold:
 - Both are set to different values which are both not `'auto'`.
 - Both are set to `'auto'`.

In these cases the model is segmented using a method similar to the hysteresis threshold method used in `edges_image`. For more information about the hysteresis threshold method, see `hysteresis_threshold`.

Note, such a contrast is not used in case of training with XLD. For more information about contrast and its impact on shape model matching, we refer to the "Solution Guide II-B – Matching".

In certain cases, it might happen that the automatic determination of the contrast thresholds is not sufficient. For example, a manual setting of these parameters should be preferred if certain model components should be included or suppressed due to application-specific reasons or if the object features several different contrasts. The contrast thresholds should be verified using `inspect_shape_model` before calling `train_generic_shape_model`.

- `'contrast_high'`:
Determines together with `'contrast_low'` the gray value difference a pixel must have to be considered as being part of the model, see the explanation above. In case of a hysteresis threshold this parameter sets the maximum.
Possible values: `'auto'`, 90, 80.
Restriction: Not used in case of training with XLD.
Default: `'auto'`.
- `'contrast_low'`: Determines together with `'contrast_high'` the gray value difference a pixel must have to be considered as being part of the model, see the explanation above. In case of a hysteresis threshold this parameter sets the minimum. *Possible values:* `'auto'`, 10, 20.
Restriction: Not used in case of training with XLD.
Default: `'auto'`.

Rotation Shape models are created with a rotation range starting at 0 and ending at 6.28 ($=2\pi$), which can be restricted during the search. The search space, thus discretization steps for the angles can be modified using:

- **'angle_step':**

Determines the step length within the selected range of angles. Its value should be chosen based on the size of the object. Smaller models do not have many different discrete rotations in the image, and hence it is recommended to choose larger values for smaller models. If set to *'auto'*, its value is estimated during the call of `train_generic_shape_model`. The set value is clipped to a maximal value of $0.20 (= \frac{\pi}{16})$.

Suggested values: *'auto'*, 0.1, 0.2.

Note: Modifications necessitate a model training.

Default: *'auto'*.

Scaling The search space, thus discretization steps for the scaling can be modified using scaling parameters. Which ones can be set depends on the type of scaling, see the overview in the following table. A scaling value of 1.0 corresponds to the original size of the model in the according direction.

GenParamName	isotropic scaling	anisotropic scaling
'iso_scale_max'	x	
'iso_scale_min'	x	
'iso_scale_step'	x	
'scale_row_max'		x
'scale_row_min'		x
'scale_row_step'		x
'scale_column_max'		x
'scale_column_min'		x
'scale_column_step'		x

- **'iso_scale_max':**

Determines the maximum of the range of possible isotropic scaling for which the model is searched.

Suggested values: 1.0, 1.1, 1.2.

Default: 1.0.

- **'iso_scale_min':** Determines the minimum of the range of possible isotropic scaling for which the model is searched.

Suggested values: 1.0, 0.9, 0.8.

Default: 1.0.

- **'iso_scale_step':** Determines the step length within the selected range of isotropic scales. The value *'auto'* means its value is estimated during the call of `train_generic_shape_model`.

- **'scale_row_max':** Determines the maximum of the range of possible scaling in row direction for which the model is searched.

Suggested values: 1.0, 1.1, 1.2.

Default: 1.0.

- **'scale_row_min':** Determines the minimum of the range of possible scaling in row direction for which the model is searched.

Suggested values: 1.0, 0.9, 0.8.

Default: 1.0.

- **'scale_row_step':** Determines the step length within the selected range of scales in row direction. The value *'auto'* means its value is estimated during the call of `train_generic_shape_model`.

- **'scale_column_max':** Determines the maximum of the range of possible scaling in column direction for which the model is searched.

Suggested values: 1.0, 1.1, 1.2.

Default: 1.0.

- **'scale_column_min':** Determines the minimum of the range of possible scaling in column direction for which the model is searched.

Suggested values: 1.0, 0.9, 0.8.

Default: 1.0.

- **'scale_column_step':** Determines the step length within the selected range of scales in column direction. The value *'auto'* means its value is estimated during the call of `train_generic_shape_model`.

Metric

- *'metric'*:

Determines the conditions under which the model is recognized in the image. Supported values for *'metric'* are:

- *'auto'*: The value is determined during the call of `train_generic_shape_model` depending if the training is done using an image (*'use_polarity'*) or XLDs (*'ignore_local_polarity'*).
- *'use_polarity'*: An instance in the image and the model must have the same contrast.
Restriction: Only applied to single-channel images. In case of multichannel images, only the first channel is used (without error message).
Example: The model has been created with a bright object on a dark background. Only instances are found if they are also brighter than the background.
- *'ignore_global_polarity'*:
An instance is found in the image also if the contrast reverses globally. This mode increases the runtime of `find_generic_shape_model` slightly compared to *'use_polarity'*.
Restriction: Only applied to single-channel images. In case of multichannel images, only the first channel is used (without error message).
Example: The model has been created with a bright object on a dark background. Instances are found if they are brighter or darker than the background.
- *'ignore_local_polarity'*:
An instance is found even if the contrast changes locally. This mode increases the runtime of `find_generic_shape_model` significantly compared to *'use_polarity'*.
It is usually recommendable to create several models that reflect the possible contrast variations of the object and to match them simultaneously.
Restriction: Only applied to single-channel images. In case of multichannel images, only the first channel is used (without error message).
Example: The model or instance contains a part with medium gray values, within which either darker or brighter sub-objects may lie.
- *'ignore_color_polarity'*:
An instance is found even if the color contrast changes locally. This mode can increase the runtime of `find_generic_shape_model` significantly compared to *'use_polarity'*.
This metric can be used for images of an arbitrary number of channels, which do not need to contain a spectral subdivision of the light (like in an RGB image). For single-channel images it has the same effect as *'ignore_local_polarity'*. The number of channels is allowed to differ from the training with `train_generic_shape_model` to the search with `find_generic_shape_model`.
Example: Instances are found even if parts of the object can change their color, e.g., from red to green.

Restriction: Using XLDs, resetting the metric requires that the edge-direction information is available as XLD contour attribute. For more information see `set_shape_model_metric`.

Default: *'auto'*.

Size

- *'min_size'*:

Determines the minimum number of points a model component must have in order to be considered. Thus, components having fewer points than *'min_size'* are suppressed. As *'min_size'* is applied on the extent of the components, the derived model contours can still be smaller than the specified minimum size. This threshold for the minimum size is divided by two for each successive pyramid level. The effect of this parameter can be checked in advance with `inspect_shape_model`.

If set to *'auto'*, its value is estimated during the call of `train_generic_shape_model`.

Restriction: Not used in case of training with XLD.

Default: *'auto'*.

- *'optimization'*:

Determines the number of points by which the model is reduced. This reduction can be useful for particularly large models. Possible values:

- *'auto'*: The number of points is automatically determined by `train_generic_shape_model`.
- *'none'*: All model points are stored.
- *'point_reduction_low'*: The number of points is reduced to roughly $\frac{1}{2}$.
- *'point_reduction_medium'*: The number of points is reduced to roughly $\frac{1}{3}$.
- *'point_reduction_high'*: The number of points is reduced to roughly $\frac{1}{4}$.

In case the number of model points is reduced it may be necessary to set the parameter *'greediness'* to a smaller value, e.g., 0.7 or 0.8. Note, for small models reducing the number of model points usually does not speed up the search as more potential instances will be examined.

Default: 'auto'.

Image Pyramid

- *'num_levels'*:

Number of considered image pyramid levels. Its value must be chosen such that the model is still recognizable and contains a sufficient number of points (at least four) on the highest pyramid level. This can be checked using the output of `inspect_shape_model`. It is advisable to set a value as large as possible as it reduces the runtime to find an instance significantly.

If set to *'auto'*, its value is estimated during the call of `train_generic_shape_model`.

It can happen that the automatically determined value does not suit. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or only with very low values for the parameters *'min_score'* or *'greediness'*. If the number of pyramid levels is chosen too small, the time required to find the model in `find_generic_shape_model` may increase. In both cases, the number of pyramid levels should be selected using the output of `inspect_shape_model`.

Default: 'auto'.

Naming

- *'model_identifier'*:

Overwrites the current identifier string with `GenParamValue`. The given identifier should be unique to avoid ambiguities at e.g., a later match retrieval with `get_generic_shape_model_result`.

Restriction: *'model_identifier'* must be a non-empty string. The following words are reserved and cannot be used as identifier names: *'all'*, *'best'*.

Default: The string which is automatically set at the shape model creation.

Finding Model Instances

In this paragraph we list parameters modifying the search of a `ModelID`. Modifying these parameters do not necessitate a model training, except they are set from a not-estimated value to a value leading to an automatic estimation during `train_generic_shape_model`. The descriptions of these parameters contain a corresponding note. The supported parameters `GenParamName` are:

1. Modify the Instance

Rotation

- *'angle_start'*:

Determines the start of the range of possible rotations for which the model is searched.

Suggested values: 0.0, -3.14, 3.14.

Default: 0.0.

- *'angle_end'* Determines the end of the range of possible rotations for which the model is searched.

Suggested values: 0.0, 3.14, 6.28.

Default: 6.28 (= 2π).

Example: *'angle_start'* = *'-rad(10)'*, *'angle_end'* = *'rad(10)'* searches for matches in the range from `[rad(350), rad(360)]` to `[0, rad(10)]`.

Scaling The scaling range specified for the trained model can be restricted further for the search. For these parameters the value *'auto'* means that they do not restrict the according range.

Note, that these restrictions can only be applied if the search space is further limited. Thus, a smaller maximum and a higher minimum scaling parameter needs to be set. Otherwise, the model has to be trained anew with adjusted scaling parameters.

GenParamName	isotropic scaling	anisotropic scaling
'restrict_iso_scale_max'	x	
'restrict_iso_scale_min'	x	
'restrict_scale_row_max'		x
'restrict_scale_row_min'		x
'restrict_scale_column_max'		x
'restrict_scale_column_min'		x

- **'restrict_iso_scale_max':**
Determines a possibly restricted maximum of the range of possible scaling for which the model is searched.
Suggested values: 'auto', 1.1, 1.2.
Default: 'auto'.
- **'restrict_iso_scale_min':**
Determines a possibly restricted minimum of the range of possible scaling for which the model is searched.
Suggested values: 'auto', 0.9, 0.8.
Default: 'auto'.
- **'restrict_scale_row_max':**
Determines a possibly restricted maximum of the range of possible scaling in row direction for which the model is searched.
Suggested values: 'auto', 1.1, 1.2.
Default: 'auto'.
- **'restrict_scale_row_min':**
Determines a possibly restricted minimum of the range of possible scaling in row direction for which the model is searched.
Suggested values: 'auto', 0.9, 0.8.
Default: 'auto'.
- **'restrict_scale_column_max':**
Determines a possibly restricted maximum of the range of possible scaling in column direction for which the model is searched.
Suggested values: 'auto', 1.1, 1.2.
Default: 'auto'.
- **'restrict_scale_column_min':**
Determines a possibly restricted minimum of the range of possible scaling in column direction for which the model is searched.
Suggested values: 'auto', 0.9, 0.8.
Default: 'auto'.

Deformation

- **'max_deformation':**
Determines by how much an object is allowed to deviate from the model in order to be considered as a match. The maximal allowable object deformation is specified in pixels. A value of 0 means no deformation is allowed during the search.
Example: An object with a shape deformed by up to 2 pixels with respect to the shape of the model can be found with *'max_deformation' = 2*.
Increasing the value for *'max_deformation'* often results in an increased runtime.
Furthermore, increasing the value for *'max_deformation'* increases the risk of obtaining unwanted matches. This is especially the case for small objects or objects with fine structures because they lose their characteristic shape, which is important for a robust search.
Interplay with *'subpixel'*: When deformation is allowed (thus, a value larger 0 is set), the score computation depends on the possible subpixel refinement. In most cases the score changes if a least-squares adjustment is set. Using an adjustment the score might increase when increasing the maximum deformation because then for the model points more corresponding image points can be found.
Default: 0.

2. Sort out Found Matches

- *'min_score'*:

Determines the minimum score a potential match must have to be regarded as model instance in the image. The larger *'min_score'* is chosen, the faster is the search. If the model can be expected never to be occluded in the images, *'min_score'* may be set as high as 0.8 or even 0.9. If the matches are not tracked to the lowest pyramid level during [find_generic_shape_model](#) it might happen that instances with a score slightly below *'min_score'* are returned.

The interplay with *'num_matches'* is explained in the description of the latter one.

Default: 0.5.

- *'num_matches'*:

Determines the maximum number of returned instances.

The value *'all'* (or 0) mean that every instance whose score is higher than *'min_score'* is returned. For the rest the interplay between *'num_matches'* and *'min_score'* as well as *'max_clutter'* (if set) is as follows:

- No clutter set:

In case there are more than *'num_matches'* instances found with a required score, only the *'num_matches'* instances with the highest scores are returned.

In case there are less than *'num_matches'* instances found with a required score, only the instances fulfilling the score requirement are returned.

- With clutter set:

In case there are more than *'num_matches'* instances found with a required score and an allowed clutter score, only the *'num_matches'* instances with the best clutter score are returned.

In case there are less than *'num_matches'* instances found with a required score and / or allowed clutter score, only the instances fulfilling the score and clutter score requirement are returned.

Tracking matches through the image pyramid depends whether clutter is set:

- No clutter set:

On each level less promising matches are rejected based on *'num_matches'*. By doing so matches may be rejected although they would have obtained a higher score on the lowest pyramid level. As a result the returned instance for e.g., *'num_matches'* set to 1 can differ from the instance with the highest score returned when more matches are returned by setting *'num_matches'* to *'all'* or a value higher 1. This explains why it might be preferable to return several instances and then select the instance with the highest score in case multiple objects with a similar score are expected, but only the one with the highest score is of interest.

- With clutter set:

No matches are rejected during tracking. As a result the runtime using clutter parameters will be at least as high as the runtime without clutter parameters but returning all matches, thus *'num_matches'* set to *'all'*.

Default: 'all'.

- *'strict_boundaries'*:

Determines whether found instances are only returned when they are strictly within the given search space boundaries (*'true'*) or not (*'false'*). Note that such a sort out appears after the reduction to the desired *'num_matches'* matches and as a consequence may lead in extreme cases to no returned match.

Compatibility: Setting this value on a model not created by [create_generic_shape_model](#) will change internal model settings. As a consequence, setting for such models *'strict_boundaries'* to *'true'* and back to *'false'* may result in a different behavior regarding matches found outside the requested search range.

Default: 'false'.

- *'max_overlap'*:

Determines by what fraction two instances may overlap at most in order to be considered as different instances and hence to be returned separately. If two instances overlap each other by more than *'max_overlap'* only the one with the higher score is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see [smallest_rectangle2](#)) of the found instances. *'max_overlap'* set to 0 means the returned instances may not overlap at all, while for *'max_overlap' = 1* all instances are returned, independent of possible overlapping. For more information about *'max_overlap'*, we refer to the "Solution Guide II-B - Matching".

Restriction: $0 \leq 'max_overlap' \leq 1$.

Default: 0.5.

- *'max_overlap_global_enable'*:

Determines whether the overlap is computed for all found instances regardless of the model (*'true'*) or not (*'false'*). I.e., the overlap of an instance is computed to the found instances of all models and a larger overlap leads to an elimination of this instance. For detailed information on the overlap computation see *'max_overlap'*.

It is important to note that the global overlap is applied to all models that are used in a search even if only one model has enabled *'max_overlap_global_enable'*.

The value used for the maximum allowed global overlap is determined as the minimum of the values set for *'max_overlap'* of all passed models.

List of values: *'true'*, *'false'*.

Default: *'false'*.

- *'max_clutter'*:

Determines the maximal clutter score a potential match can have to be regarded as model instance in the image. Of course this applies only to models where clutter is considered, thus *'use_clutter'* is set to *'true'*.

Default: 0.0.

3. Gray Value Treatment

- *'min_contrast'*:

Determines the minimal contrast (gray value difference to neighboring pixels) a point in a search image must at least have in order to be compared with the model. The main use of this parameter is to exclude noise, from the matching process. The operator [estimate_noise](#) can be used to assess the noise.

Example: The gray values fluctuate within a range of 10 gray levels. In this case it is advisable to set *'min_contrast' = 10*.

Multichannel images: For a search in a multichannel image using *'metric'* set to *'ignore_color_polarity'*, the noise in one channel must be multiplied by the square root of the number of channels to determine *'min_contrast'*.

Example: The gray values of a 3 channel image fluctuate within a range of 10 gray levels in a single channel. In this case it is advisable to set *'min_contrast' = 17*.

Note, *'min_contrast'* must be smaller than the contrast threshold set using *'contrast_low'* and *'contrast_high'*, see above.

The value *'auto'* means its value is estimated during the call of [train_generic_shape_model](#) based on the noise in the model image. Consequently, for a meaningful automatic determination the noise in the model image must be similar to the one in the images used during recognition.

Training: Changing this value to *'auto'* necessitates a training of the shape model.

Possible values: *'auto'*, 10, 20.

Default: *'auto'*.

- *'border_shape_models'*:

Determines whether the shape model [ModelID](#) to be found with, e.g., [find_generic_shape_model](#), may lie partially outside the image (i.e., whether it may cross the image border, independent of the domain). The value *'system'* means the model uses the system-wide set value set by [set_system](#) for the parameter *'border_shape_models'*.

List of values: *'system'*, *'true'*, *'false'*.

Default: *'system'*.

4. Refinement

- *'subpixel'*:

Determines which type of subpixel refinement should be carried out. Possible values:

- *'none'*: The pose of the model is only determined with pixel accuracy and the angle resolution that was specified with *'angle_step'*.
- *'interpolation'*: The pose of the model is interpolated from the score function. This mode features very low computation costs.
- *'least_squares'*: The pose of the model is refined using least squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points.
- *'least_squares_high'*: The pose of the model is refined using least squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. More minimization iterations are allowed than for *'least_squares'*, resulting in a possibly increased runtime.
- *'least_squares_very_high'*: The pose of the model is refined using least squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. More minimization iterations are allowed than for *'least_squares_high'*, resulting in a possibly increased runtime.

The interplay with `'max_deformation'` is explained in the description of latter one.

Default: 'least_squares'.

- `'greediness'`:
Determines how “greedily” the search should be carried out. A higher value results in a faster search but a less safe search heuristic.
Restriction: $0 \leq \text{'greediness'} \leq 1$.
Default: 0.9.

5. Image Pyramid

- `'pyramid_level_highest'`:
Determines the highest level of the image pyramid used in the search. This allows to lower the highest image pyramid level set by the model uses during a search. Its value can not be higher than the highest image pyramid level of the model, which is set through `'num_levels'`. As a consequence, `'pyramid_level_highest'` is clipped. The value `'auto'` means no lowering is applied, thus the model uses the highest pyramid level set through `'num_levels'`.
Default: 'auto'.
- `'pyramid_level_lowest'`:
Determines the lowest level of the image pyramid to which the found matches are tracked. Not tracking the matches down to the lowest level decreases the runtime of the search. But in general the higher the lowest level, the lower the accuracy of the extracted pose parameters. In extreme cases this can even lead to finding wrong instances of that the desired accuracy cannot be achieved.
Default: 1.
- `'pyramid_level_robust_tracking'`:
Determines whether the so-called “increased tolerance mode” is active (`'true'`) or not (`'false'`). In this mode the lowest image pyramid level on which at least one match can be found is automatically determined during the search. This mode can be helpful in case of input images of poor quality, e.g., defocused, deformed, or noisy images. In such cases the edge information on the lowest image pyramid level may be missing or deformed and as a consequence no instances of the shape model can be found. Nevertheless, the edge information may be sufficient on higher pyramid levels. The selection of the suitable pyramid level, i.e., the lowest pyramid level on which at least one instance of the shape model can be found, depends on the model and on the input image. Of course the restrictions on accuracy and robustness mentioned for `'pyramid_level_lowest'` occur. *Example: 'pyramid_level_highest' is set to 4, 'pyramid_level_lowest' is set to 2, and 'pyramid_level_robust_tracking' is set to 'true'. Now the matching starts at the fourth pyramid level and tracks the matches down to the second lowest pyramid level. If no instance of the model can be found on the pyramid level 2, but matches have been obtained at a higher level, the lowest pyramid level is determined on which at least one instance of the model is found. The instances of this pyramid level will then be returned.*
Default: 'false'.

6. Clutter

The following parameters are used to specify the clutter region. Note that for this the clutter region has to be set beforehand using `set_generic_shape_model_object`.

- `'use_clutter'`:
Determines whether the model `ModelID` considers clutter parameters (`'true'`) or not (`'false'`). The runtime using clutter parameters will be at least as high as the runtime without clutter parameters but returning all matches, thus `'num_matches'` set to `'all'`.
List of values: 'false', 'true'.
Default: 'false'.
- `'clutter_contrast'`:
Determines the minimal contrast which edges in the clutter region must have in order to be counted as clutter.
The polarity of the found clutter edges is ignored, i.e., bright objects on a dark background will yield the same clutter score as dark objects on a bright background, independent of the parameter `'metric'` of the shape model.
For the value `'auto'` the contrast will be estimated automatically. Note, a suitable estimation requires that the defining region is representative. We recommend to check if the estimated value is suitable and adapt it otherwise.
Please note that clutter scores are strongly affected by illumination variations.
Possible values: 'auto', 5, 10.

Restriction: 'clutter_contrast' must be larger or equal to 'min_contrast'.

Default: 'auto'.

Attention: A suitable automatic estimation is not possible for shape models generated from XLD contours. Therefore, in such a case the estimated value is set to 'min_contrast', see also the section "Automatic modifications" below.

- 'max_clutter':

The value 'max_clutter' specifies the maximum clutter score that a match can have in order to be accepted.

Note, the value of this parameter has no effect on the runtime.

Value range: [0.0, 1.0].

Default: 0.0.

- 'clutter_hom_mat_2d':

The clutter region is set relative to the model. The transformation matrix 'clutter_hom_mat_2d' maps the model origin to the position of the model instance (or rather its center of gravity) in the image when the clutter region has been set using [set_generic_shape_model_object](#).

Possible values:

- 'auto': Value is estimated automatically. The clutter region is set relative to the model in the template image used by [set_generic_shape_model_object](#).
- Transformation matrix: Transformation is given by the user.

Default: 'auto'.

- 'clutter_border_mode':

With 'clutter_border_mode' the behavior of the clutter score can be influenced in cases where the clutter region of a found match is not entirely contained in the image domain. The corresponding values for 'clutter_border_mode' are:

- 'clutter_border_average':
When 'clutter_border_average' is set, the hidden part of the clutter region is assumed to be filled on average as is its visible part. If the clutter region is not visible at all, the clutter score of the found match is set to 0.0.
- 'clutter_border_empty':
When 'clutter_border_empty' is set, the clutter region is assumed to be clutter-free where it is not visible.

Note that 'clutter_border_average' may result in higher clutter scores than 'clutter_border_empty' even if the match is not located at the border of the image domain.

List of values: 'clutter_border_average', 'clutter_border_empty'.

Default: 'clutter_border_average'.

7. Regarding the Output

- Origin:

The origin (reference point) is specified relative to the center of gravity of the domain (region) of the image that was used to train the shape model with [train_generic_shape_model](#). Hence, an origin of (0,0) means that the center of gravity of the domain of the template image is used as the origin. The origin can be set to a new value using the following parameters:

- 'origin_row': Determines the column coordinate of a new, shifted center of origin.
Default: 0.
- 'origin_column': Determines the column coordinate of a new, shifted center of origin.
Default: 0.

Example: Setting 'origin_column' = -20 and 'origin_row' = -40 results in a new origin lying in the upper left of the center of gravity of the model. Please note that changing the origin influences the used transformation matrices, i.e., the 'clutter_hom_mat_2d' set by the user and the calculated 'hom_mat_2d' of a match.

- 'prepare_contours_for_visualization'

Determines whether a found contour of a match should be prepared in [find_generic_shape_model](#) and returned in MatchResultID ('true') or not ('false'). Deactivating 'prepare_contours_for_visualization' decreases the runtime. For how to query the generated contour, see the documentation of [get_generic_shape_model_result_object](#).

List of values: 'true', 'false'.

Default: 'true'.

- *'prepare_clutter_region_for_visualization'*
Determines whether the clutter region of a match should be prepared in [find_generic_shape_model](#) and returned in `MatchResultID` ('true') or not ('false'). Deactivating *'prepare_clutter_region_for_visualization'* decreases the runtime. For how to query the generated clutter region, see the documentation of [get_generic_shape_model_result_object](#).
List of values: 'true', 'false'.
Default: 'true'.
- *'time_measurement'*
Determines whether during the search, the time spent in individual parts should be measured. The individual times are returned in `MatchResultID`, see [get_generic_shape_model_result](#).
List of values: 'pipeline', 'false'.
Default: 'false'.

Computational Resources during a Search

In this paragraph we list parameters concerning technical influences when searching the model `ModelID`. Supported `GenParamName` are:

- *'model_cache'*:
Determines whether an internal cache based on temporary memory is used ('true') or not 'false' during e.g., [find_generic_shape_model](#). Switching the *'model_cache'* off (by setting 'false') sometimes results in slightly longer execution times but constantly smaller memory footprint.
The size of the cache depends on the search space, thus if the search space contains many discretization steps. This means a fine search grid with small `step` values covering large ranges for `start` to `end` values results in a large memory consumption.
Default: 'true'.
- *'timeout'*:
Determines the maximum runtime of the operators used to find the shape model `ModelID` (e.g., [find_generic_shape_model](#)). The temporal accuracy depends on several factors including the size of the model, the speed of the used computer, and the *'timer_mode'* set via [set_system](#). Be aware that the runtime of the search increases by up to 10 percent with activated timeout.
The value for *'timeout'* must be given in milliseconds. To disable the timeout you can either use a negative value or 'false'.
Possible values: 'false', -1, 100.
Default: 'false'.

Automatic modifications

The following parameters are subject to automatic modifications without further notice:

- *'num_levels'*:
If a number of levels is set such that on the asked levels not enough model points are generated, the number of pyramid levels is reduced internally until enough model points are found on the highest pyramid level.
If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is already too small on the lowest pyramid level, [train_generic_shape_model](#) returns with an error message.
- Parameters determining a *step_size*:
In case the range is not a multiple of the *step_size*, latter one is modified accordingly.
Examples: 'angle_step', 'iso_scale_step'.
- `start` and `end` value of a specified range:
To ensure that for model instances in the exact model position are returned by [find_generic_shape_model](#), ranges may be modified as follows: If there is no positive integer value `n` such that the *start* value plus `n` times the *step_size* gives 0.0 (for angles) and 1.0 (for scalings), respectively, the *start* value is decreased by up to one *step_size* and the *end* value increased such that the total range is increased by exactly one *step_size*.
Examples: 'angle_start', 'restrict_iso_scale_max'.
- *'clutter_hom_mat_2d'*: Changing the origin (*'origin_row'* and *'origin_column'*) influences the used transformation matrices, i.e., the *'clutter_hom_mat_2d'* set by the user.

- *'clutter_contrast'*: If *'min_contrast'* is changed such that it gets bigger than *'clutter_contrast'*, *'clutter_contrast'* is increased if the user set the value *'auto'*.

Note that the transformations are treated internally such that the scalings are applied first, followed by the rotation. Therefore, the model should usually be aligned such that it appears horizontally or vertically in the model image.

Parameters

- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the shape model.
- ▷ **GenParamName** (input_control) attribute.name-array $\leadsto$ string
Parameter name.
Default: 'min_score'
List of values: GenParamName $\in$ {'angle_end', 'angle_start', 'angle_step', 'border_shape_models', 'clutter_border_mode', 'clutter_contrast', 'clutter_hom_mat_2d', 'contrast_high', 'contrast_low', 'greediness', 'iso_scale_max', 'iso_scale_min', 'iso_scale_step', 'max_clutter', 'max_deformation', 'max_overlap', 'max_overlap_global_enable', 'metric', 'min_contrast', 'min_score', 'min_size', 'model_cache', 'model_identifier', 'num_levels', 'num_matches', 'optimization', 'origin_column', 'origin_row', 'prepare_contours_for_visualization', 'prepare_clutter_region_for_visualization', 'pyramid_level_highest', 'pyramid_level_lowest', 'pyramid_level_robust_tracking', 'restrict_iso_scale_max', 'restrict_iso_scale_min', 'restrict_scale_column_max', 'restrict_scale_column_min', 'restrict_scale_row_max', 'restrict_scale_row_min', 'scale_column_max', 'scale_column_min', 'scale_column_step', 'scale_row_max', 'scale_row_min', 'scale_row_step', 'strict_boundaries', 'subpixel', 'time_measurement', 'timeout', 'use_clutter'}
- ▷ **GenParamValue** (input_control) attribute.value-array $\leadsto$ real / integer / string
Parameter value.
Default: 0.5
Suggested values: GenParamValue $\in$ {-3.14, -1.57, -0.79, -0.39, 0.0, 0.39, 0.79, 1.57, 3.14}

Result

If the parameters are valid, the operator `set_generic_shape_model_param` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_generic_shape_model`

Possible Successors

`get_generic_shape_model_param`, `train_generic_shape_model`,
`find_generic_shape_model`

Module

Matching

```
set_shape_model_clutter ( ClutterRegion : : ModelID, HomMat2D,
                        ClutterContrast, GenParamName, GenParamValue : )
```

Set the clutter parameters of a shape model.

`set_shape_model_clutter` sets the clutter parameters of the shape model `ModelID`. In particular, a region is defined relative to the model contours, in which no (or too faint) clutter edges should occur in the search image.

This is helpful, e.g., if it is a special characteristic of the model that, in specific parts near to the model, structures are missing.

For example, within the HDevelop example program `find_shape_model_clutter.hdev`, the model corresponds to a ball in a ball grid array (BGA). As the ball grid array represents a repeating pattern, many matches are returned when matching is applied without considering the neighborhood of the model. By defining a clutter region, the search can be restricted to specific instances of the model.

(1) Image of ball grid array, (2) shape model of a single ball of the array (orange), (3) matching result without using clutter parameters (green), (4) defining the clutter region (yellow) relative to the model (orange), (5) matching result using clutter parameters (green).

For matches found in a search image, edges within the clutter region increase the resulting clutter scores. These are returned by `find_shape_model`, `find_scaled_shape_model`, `find_aniso_shape_model`, `find_shape_models`, `find_scaled_shape_models`, and `find_aniso_shape_models` in the parameter `Score`, following the common values measuring how much of the model is visible in the image. Note that the input parameter `MinScore` of those operators additionally expects information specifying the maximum clutter score up to which matches should be returned. For more information regarding the setting of `MinScore`, please refer to the respective operator reference.

To define the clutter region relative to the model contours, you need the region `ClutterRegion` and the transformation matrix `HomMat2D` that maps the model contours to the respective position where the object appears in an image. Typically, you obtain them by searching for a model instance in an image, e.g., with the operator `find_shape_model`. Then, the transformation matrix can be determined with the procedure `get_hom_mat2d_from_matching_result` using the respective output parameters of the search. The region `ClutterRegion` is specified within the same image. Note that `ClutterRegion` should contain the regions around the superfluous edges that are typical for all expected manifestations of the matches. We recommend that the clutter region is chosen larger than necessary when large scale ranges are searched. Furthermore, choosing the clutter region not too near to the expected model contours can increase the robustness.

The parameter `ClutterContrast` determines the contrast the edges in the clutter region must have in order to be counted as clutter. In many applications, the parameter `Contrast`, which has been used to create the shape model, is also a reasonable choice for `ClutterContrast`. `ClutterContrast` may not be smaller than the parameter `MinContrast` of the shape model, otherwise an error is raised at runtime. The polarity of the found clutter edges is ignored, i.e., bright objects on a dark background will yield the same clutter score as dark objects on a bright background, independent of the parameter `Metric` of the shape model. Please note that of all shape-based matching results, clutter scores are affected the most when a variation of illumination occurs.

With `GenParamName` set to `'clutter_border_mode'`, the behavior of the clutter score can be influenced in cases where the clutter region of a found match is not entirely contained in the image domain. The corresponding values for `'clutter_border_mode'` (`GenParamValue`) can be `'clutter_border_average'` or `'clutter_border_empty'`.

- `'clutter_border_average'`:

When `GenParamValue` is set to `'clutter_border_average'` (default), the hidden part of the clutter region is assumed to be filled on average as is its visible part. If the clutter region is not visible at all, the clutter score of the found match is set to `0.0`.

- `'clutter_border_empty'`:

When `GenParamValue` is set to `'clutter_border_empty'`, the clutter region is assumed to be empty where it is not visible.

Note that `GenParamValue` set to `'clutter_border_average'` results in higher clutter scores even if the match is not located at the border of the image domain.

The use of clutter parameters can be disabled and enabled by calling `set_shape_model_param`. For newly created shape models, the use of clutter parameters is disabled. After calling `set_shape_model_clutter`, the use of clutter parameters is enabled. Depending on the activation status for the use of clutter parameters, the find operators, e.g., `find_shape_model`, expect a different number of entries in the input parameter `MinScore`. The set clutter parameters and the value of `'use_clutter'` can be queried using the operator `get_shape_model_clutter`.

Parameters

- ▷ **ClutterRegion** (input_object) region $\leadsto$ object
Region where no clutter should occur.
- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.
- ▷ **HomMat2D** (input_control) hom_mat2d $\leadsto$ real
Transformation matrix.
- ▷ **ClutterContrast** (input_control) number $\leadsto$ integer
Minimum contrast of clutter in the search images.
Default: 128
- ▷ **GenParamName** (input_control) attribute.name(-array) $\leadsto$ string
Parameter names.
List of values: `GenParamName` $\in$ `{'clutter_border_mode'}`
- ▷ **GenParamValue** (input_control) attribute.value(-array) $\leadsto$ real / integer / string
Parameter values.
List of values: `GenParamValue` $\in$ `{'clutter_border_empty', 'clutter_border_average'}`

Example

```
*
* Create a shape model.
read_image (ImageModel, '/bga_gap/bga_gap_01.png')
gen_circle (ROI, 753.869, 551.624, 28.4027)
reduce_domain (ImageModel, ROI, ImageReduced)
create_aniso_shape_model (ImageReduced, 'auto', rad(0), rad(0), 'auto', \
                          0.95, 1.05, 'auto', 0.95, 1.05, 'auto', 'auto', \
                          'use_polarity', 'auto', 'auto', ModelID)

*
* Specify the clutter parameters.
find_aniso_shape_model (ImageModel, ModelID, rad(0), rad(0), 0.95, 1.05, \
                      0.95, 1.05, 0.83, 0, 0.0, 'least_squares', 0, 0.0, \
                      Row, Column, Angle, ScaleR, ScaleC, Score)
get_hom_mat2d_from_matching_result (Row[0], Column[0], Angle[0], ScaleR[0], \
                                   ScaleC[0], HomMat2D)

*
gen_circle (ROI_0, 700.655, 548.666, 21.6273)
gen_circle (ROI_1_0, 810.655, 550.611, 21.6273)
union2 (ROI_0, ROI_1_0, ClutterRegion)

*
ClutterContrast := 12

*
* Set the clutter parameters into shape model.
set_shape_model_clutter (ClutterRegion, ModelID, HomMat2D, ClutterContrast, \
                        [], [])

*
* Use the shape model to detect objects with a small amount of clutter
read_image (Image, '/bga_gap/bga_gap_02.png')
MaxClutter := 0.09
find_aniso_shape_model (Image, ModelID, rad(0), rad(0), 0.95, 1.05, 0.95, \
                      1.05, [0.83, MaxClutter], 0, 0.0, 'least_squares', \
```

```

[4, 3], 0.0, Row, Column, Angle, ScaleR, ScaleC, \
Score)
*
* Visualize the matches
dev_display_shape_matching_results (ModelID, ['green', 'red'], Row, Column, \
Angle, ScaleR, ScaleC, 0)
Clutter := Score[|Score|/2:|Score|-1]
Score := Score[0:|Score|/2-1]
dev_inspect_ctrl ([Score, Clutter])

```

Result

If the parameters are valid, the operator `set_shape_model_clutter` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

`set_shape_model_param`

Module

Matching

set_shape_model_metric (Image : : ModelID, HomMat2D, Metric :)

Set the metric of a shape model that was created from XLD contours.

`set_shape_model_metric` changes the value of the parameter `Metric` that was selected during the creation of the shape model `ModelID` from XLD contours. For this, the polarity of the model edges is determined based on the image `Image`. The transformation that maps the model edges to the image position where the respective object appears is given in `HomMat2D`.

The parameter `Metric` determines the conditions under which the model is recognized later in the search image. If `Metric = 'use_polarity'`, the object in the image and the model must have the same contrast. If, for example, the model is a bright object on a dark background, the object is found only if it is also brighter than the background. If `Metric = 'ignore_global_polarity'`, the object is found in the image also if the contrast reverses globally. In the above example, the object hence is also found if it is darker than the background. The runtime of `find_generic_shape_model` will increase slightly in this case.

It must be ensured that the object edges in the `Image` have the same (or inverse) polarity as the object edges in the image in which the object must be searched later. Especially, the object must not be occluded in the `Image` and the background must be either brighter than the object or darker. Otherwise, the determined polarity of the model edges will not represent the polarity of the object edges during the search. Note that only the polarity of the edges is determined, not their contrast. Note also that the polarity is determined from a single-channel image, only. If a multichannel image is passed in `Image`, only the first channel will be used (and no error message will be returned).

The transformation defined by the matrix `HomMat2D` maps the model contours to the respective position where the object appears in the `Image`. It can be obtained by finding the object in the `Image`, e.g., with the operator `find_generic_shape_model` and determining the respective transformation matrix with the procedure `get_hom_mat2d_from_matching_result`. The operator `set_shape_model_metric` ignores an origin that was set by `set_shape_model_origin` and always assumes (0,0) as the origin. Hence, when finding the object in the `Image`, all other operators must have the origin at the point (0,0). Therefore, `set_shape_model_origin` must be called with (0,0) as the origin.

A typical proceeding is to read the XLD contours from file. Since these XLD contours do not provide polarity information, the shape model must be created from the XLD contours by setting the parameter `Metric` to `'ignore_local_polarity'`. Then, in a first search image the model is recognized. The transformation that maps the model contours to the position of the object in the search image can be determined from the matching result. To verify the match interactively, the model contours can be mapped to this position. If the matching result is correct, the value of the parameter `Metric` can be changed, e.g., to `'use_polarity'`. This leads to a faster and more robust recognition in the following images.

Attention

`set_shape_model_metric` can only be used with shape models that were created from XLD contours.

Parameters

- ▷ **Image** (input_object) singlechannelimage $\leadsto$ object : byte / uint2
Input image used for the determination of the polarity.
- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.
- ▷ **HomMat2D** (input_control) hom_mat2d $\leadsto$ real
Transformation matrix.
- ▷ **Metric** (input_control) string $\leadsto$ string
Match metric.
Default: `'use_polarity'`
List of values: `Metric` $\in$ `{'use_polarity', 'ignore_global_polarity'}`

Example

```
*
* Read the contours from file
read_contour_xld_dxf (Contours, 'metal-part-01', [], [], DxfStatus)
*
* Scale the contours such that they correspond to the image
hom_mat2d_identity (HomMat2DIdentity)
hom_mat2d_scale (HomMat2DIdentity, 3.35, 3.35, 0, 0, HomMat2DScale)
affine_trans_contour_xld (Contours, ContoursAffineTrans, HomMat2DScale)
*
* Create the shape model with Metric='ignore_local_polarity'
create_generic_shape_model (ModelID)
train_generic_shape_model (ContoursAffineTrans, ModelID)
*
* Get an image of the object and try to find the object in this image
read_image (Image, 'metal-parts/metal-parts-01')
find_generic_shape_model (Image, ModelID, MatchResultID, NumMatchResult)
*
* Visualize the match
get_generic_shape_model_result_object (Objects, MatchResultID, 'all', \
                                     'contours')
```

```

stop()
get_generic_shape_model_result (MatchResultID, 'all', 'hom_mat_2d', \
                                HomMat2D)
*
* Set the matching metric to 'use_polarity', based on the position
* of the found object
set_shape_model_metric (Image, ModelID, HomMat2D, 'use_polarity')
*
* Use the shape model to detect the object faster and more robust
read_image (Image, 'metal-parts/metal-parts-02')
find_generic_shape_model (Image, ModelID, MatchResultID, NumMatchResult)
*
* Visualize the matches
get_generic_shape_model_result_object (Objects, MatchResultID, 'all', \
                                       'contours')

```

Result

If the parameters are valid, the operator `set_shape_model_metric` returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ModelID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

set_shape_model_origin (: : ModelID, Row, Column :)
--

Set the origin (reference point) of a shape model.

The operator `set_shape_model_origin` sets the origin (reference point) of the shape model `ModelID` to a new value. The origin is specified relative to the center of gravity of the domain (region) of the image that was used to create the shape model with [create_shape_model](#), [create_scaled_shape_model](#), or [create_aniso_shape_model](#). Hence, an origin of (0,0) means that the center of gravity of the domain of the model image is used as the origin. An origin of (-20,-40) means that the origin lies to the upper left of the center of gravity.

Parameters

- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.
- ▷ **Row** (input_control) point.y $\leadsto$ real
Row coordinate of the origin of the shape model.

▷ **Column** (input_control) point.x $\leadsto$ real
Column coordinate of the origin of the shape model.

Result

If the handle of the model is valid, the operator `set_shape_model_origin` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Successors

[train_generic_shape_model](#)

See also

[area_center](#)

Module

Matching

set_shape_model_param (: : ModelID, GenParamName, GenParamValue :)
--

Set selected parameters of the shape model.

The operator `set_shape_model_param` sets the selected parameters [GenParamName](#) in the shape model [ModelID](#). The following parameters can be modified:

'min_contrast'

Sets the minimum contrast of the object in the search images for the shape model [ModelID](#). Thereby, the value of *'min_contrast'* that was originally set, e.g., with [create_shape_model](#), is overwritten for the shape model [ModelID](#). Note that if the shape model [ModelID](#) was read from file and if this file should be changed as well, the shape model [ModelID](#) must again be written to file after the execution of the operator `set_shape_model_param`.

'timeout'

Sets the maximum runtime of the operators used to find the shape model [ModelID](#) (e.g., [find_shape_model](#)). This is especially useful in cases where a maximum cycle time has to be ensured. The *'timeout'* must be given in milliseconds. The temporal accuracy depends on several factors including the size of the model, the speed of your computer, and the *'timer_mode'* set via [set_system](#). Be aware that the runtime of the search increases by up to 10 percent with activated timeout. To disable the timeout you can either use a negative value or *'false'*.

'border_shape_models'

This parameter determines whether the shape model [ModelID](#) to be found with, e.g., [find_shape_model](#), may lie partially outside the image (i.e., whether they may cross the image border). The value of *'border_shape_models'* can be *'true'*, *'false'*, or *'system'*. The value *'system'* is the default behavior and uses the system-wide used value that was set by [set_system](#) for the parameter *'border_shape_models'*.

'use_clutter'

Disables or enables the use of clutter parameters for the shape model [ModelID](#), which have been set previously using [set_shape_model_clutter](#). The value of *'use_clutter'* can be *'true'* or *'false'*. Note that the value

of `'use_clutter'` affects the expected number of entries in the input parameter `MinScore` of the find operators. Please refer to the documentation of the different find operators, e.g., [find_shape_model](#).

For newly created shape models, the use of clutter parameters is disabled. After calling [set_shape_model_clutter](#), the use of clutter parameters is enabled. Clutter parameters and the value of `'use_clutter'` can be queried using [get_shape_model_clutter](#).

`'model_cache'`

Disables or enables the use of an internal cache based on temporary memory that is used by a shape model when it executes, e.g., [find_shape_model](#). The size of the cache depends on whether the find operation needs a big search space with many discretization steps. This means that a small `AngleStep` and `ScaleStep` and a big `AngleExtent` and a big range given by `ScaleMin` and `ScaleMax` result in a big memory consumption. Switching the `'model_cache'` off (by setting `'false'`) sometimes results in slightly longer execution times but constantly small memory footprint, particularly important in embedded applications. By default, this cache is switched on (`'true'`).

Parameters

- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.
- ▷ **GenParamName** (input_control) attribute.name-array $\leadsto$ string
Parameter names.
List of values: GenParamName $\in$ {`'min_contrast'`, `'timeout'`, `'border_shape_models'`, `'use_clutter'`, `'model_cache'`}
- ▷ **GenParamValue** (input_control) attribute.value-array $\leadsto$ real / integer / string
Parameter values.
List of values: GenParamValue $\in$ {`'true'`, `'false'`, `'system'`}

Result

If the parameters are valid, the operator `set_shape_model_param` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Matching

train_generic_shape_model (Template : : ModelID :)

Train a shape model for matching.

The operator `train_generic_shape_model` trains the shape model `ModelID` in order to find the training pattern given in `Template`.

`Template` accepts the training pattern to be of one of the following types:

Image: The domain of the image given in `Template` sets the ROI of the model.

The model origin (reference point) is defined by the center of gravity of the image domain. The origin can be reset to a different point using `set_generic_shape_model_param`.

XLD contour: XLD contours passed in `Template` should represent the gray value edges of the pattern to be searched.

The model origin (reference point) is defined by the center of gravity of the smallest axis-parallel rectangle enclosing the contours. The origin can be reset to a different point using `set_generic_shape_model_param`.

Properties of the model `ModelID` can be retrieved using `get_generic_shape_model_param` and modified using `set_generic_shape_model_param`. Note that after modifying certain parameters the model needs to be (re)trained, see `set_generic_shape_model_param`.

Parameters

- ▷ **Template** (input_object) (multichannel-)object(-array) $\leadsto$ *object*
Training image or xld.
- ▷ **ModelID** (input_control) shape_model $\leadsto$ *handle*
Handle of the shape model.

Result

If the parameters are valid, the operator `train_generic_shape_model` returns the value 2 (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `ModelID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_generic_shape_model`, `set_generic_shape_model_param`

Possible Successors

`find_generic_shape_model`

Module

Matching

write_shape_model (: : ModelID, FileName :)

Write a shape model to a file.

The operator `write_shape_model` writes a shape model to the file `FileName`. The model can be read again with `read_shape_model`. The default HALCON file extension for the shape model is 'shm'.

Parameters

- ▷ **ModelID** (input_control) shape_model $\leadsto$ handle
Handle of the model.
- ▷ **FileName** (input_control) filename.write $\leadsto$ string
File name.
File extension: .shm

Result

If the file name is valid (write permission), the operator write_shape_model returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Chapter 19

Matrix

19.1 Access

`get_diagonal_matrix ( : : MatrixID, Diagonal : VectorID )`

Get the diagonal elements of a matrix.

The operator `get_diagonal_matrix` generates a new matrix `Vector` and copies the diagonal elements of the `Matrix` to this new matrix. The `Matrix` is defined by the matrix handle `MatrixID`. The matrix `Vector` has one column and n rows, where n = number of diagonal elements. The operator returns the matrix handle `VectorID` of the matrix `Vector`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`.

If `Diagonal` = 0, the output of the `Vector` is the main diagonal of the `Matrix`.

Example:

`Diagonal` = 0

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix}$$

$$\rightarrow \text{Vector} = \begin{bmatrix} 3.0 \\ 7.0 \\ 1.0 \end{bmatrix}$$

If `Diagonal` is positive, the output `Vector` is the `Diagonal`-th super-diagonal of the `Matrix`.

Example:

`Diagonal` = 2

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 & 1.0 \\ -5.0 & 7.0 & 2.0 & 6.0 \\ -9.0 & -4.0 & 1.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{Vector} = \begin{bmatrix} -2.0 \\ 6.0 \end{bmatrix}$$

If `Diagonal` is negative, the `Diagonal`-th sub-diagonal of the `Matrix` is copied.

Example:

`Diagonal` = -1

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 & 1.0 \\ -5.0 & 7.0 & 2.0 & 6.0 \\ -9.0 & -4.0 & 1.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{Vector} = \begin{bmatrix} -5.0 \\ -4.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **Diagonal** (input_control) integer $\leadsto$ *integer*
Number of the desired diagonal.
Default: 0
Suggested values: Diagonal $\in \{-20, -10, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}$
- ▷ **VectorID** (output_control) matrix $\leadsto$ *handle*
Matrix handle containing the diagonal elements.

Result

If the parameters are valid, the operator `get_diagonal_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`set_diagonal_matrix`

Module

Foundation

get_full_matrix (: : MatrixID : Values)

Return all values of a matrix.

The operator `get_full_matrix` returns the values of all elements of the `Matrix` given by the matrix handle `MatrixID`. The output parameter `Values` is a tuple of floating point numbers and contains all values in a row-major order, i.e., line by line.

Example:

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \rightarrow \text{Values} = [3.0, 1.0, -2.0, -5.0, 7.0, 2.0, -9.0, -4.0, 1.0]$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.
- ▷ **Values** (output_control) real(-array) $\leadsto$ real
Values of the matrix elements.

Result

If the parameters are valid, the operator `get_full_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
get_sub_matrix ( : : MatrixID, Row, Column, RowsSub,
                  ColumnsSub : MatrixSubID )
```

Get a sub-matrix of a matrix.

The operator `get_sub_matrix` generates a new matrix `MatrixSub` and copies to this matrix a part of the input `Matrix` defined by the matrix handle `MatrixID`. The part of the `Matrix` is determined by the upper left corner (`Row`, `Column`) and the sub-matrix dimensions (`RowsSub`, `ColumnsSub`). The operator returns the matrix handle `MatrixSubID` of the matrix `MatrixSub`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`.

Example:

`Row = 0`, `Column = 1`, `RowsSub = 3`, `ColumnsSub = 2`

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 & 1.0 \\ -5.0 & 7.0 & 2.0 & 6.0 \\ -9.0 & -4.0 & 1.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixSub} = \begin{bmatrix} 1.0 & -2.0 \\ 7.0 & 2.0 \\ -4.0 & 1.0 \end{bmatrix}$$

Attention

The conditions $0 \leq \text{Row} < \text{size of Matrix in row direction}$, $\text{Row} + \text{RowsSub} \leq \text{size of Matrix in the row direction}$, $0 \leq \text{Column} < \text{size of Matrix in the column direction}$, and $\text{Column} + \text{ColumnsSub} \leq \text{size of matrix Matrix in the column direction}$ must be satisfied.

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.
- ▷ **Row** (input_control) integer $\leadsto$ integer
Upper row position of the sub-matrix in the input matrix.
Default: 0
Suggested values: Row $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100}
Restriction: Row $\geq$ 0
- ▷ **Column** (input_control) integer $\leadsto$ integer
Left column position of the sub-matrix in the input matrix.
Default: 0
Suggested values: Column $\in$ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100}
Restriction: Column $\geq$ 0
- ▷ **RowsSub** (input_control) integer $\leadsto$ integer
Number of rows of the sub-matrix.
Default: 1
Suggested values: RowsSub $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100}
Restriction: RowsSub $\geq$ 1
- ▷ **ColumnsSub** (input_control) integer $\leadsto$ integer
Number of columns of the sub-matrix.
Default: 1
Suggested values: ColumnsSub $\in$ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100}
Restriction: ColumnsSub $\geq$ 1
- ▷ **MatrixSubID** (output_control) matrix $\leadsto$ handle
Matrix handle of the sub-matrix.

Result

If the parameters are valid, the operator `get_sub_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_value_matrix (: : MatrixID, Row, Column : Value)

Return one ore more elements of a matrix.

The operator `get_value_matrix` returns the values of one ore more elements of the `Matrix` as a tuple of floating point numbers. The `Matrix` is given by the matrix handle `MatrixID`. The row coordinates of the elements of the `Matrix` are determined by the tuple `Row`, the column coordinates by the tuple `Column`.

Example:

`Row = [0,2,1], Column = [1,0,3]`

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 & 1.0 \\ -5.0 & 7.0 & 2.0 & 6.0 \\ -9.0 & -4.0 & 1.0 & -1.0 \end{bmatrix}$$

→ **Value** = [1.0, -9.0, 6.0]

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **Row** (input_control) integer(-array) $\leadsto$ *integer*
Row numbers of matrix elements to be returned.
Default: 0
Suggested values: Row $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}$
Restriction: Row ≥ 0
- ▷ **Column** (input_control) integer(-array) $\leadsto$ *integer*
Column numbers of matrix elements to be returned.
Default: 0
Suggested values: Column $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}$
Restriction: Column ≥ 0
- ▷ **Value** (output_control) real(-array) $\leadsto$ *real*
Values of indicated matrix elements.

Result

If the parameters are valid, the operator `get_value_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`set_value_matrix`

Module

Foundation

set_diagonal_matrix (: : MatrixID, VectorID, Diagonal :)

Set the diagonal elements of a matrix.

The operator `set_diagonal_matrix` *overwrites* the diagonal elements of the `Matrix` with the elements of the matrix `Vector`. The matrices are defined by their matrix handles `MatrixID` and `VectorID`. The matrix `Vector` must have one column and one row, n columns and one row or one column and n rows. n is the number of elements to be set in the `Matrix` (see below). If the matrix `Vector` has one column and one row, i.e., the matrix has one value, each element of the diagonal of the `Matrix` is overwritten by this value. Otherwise, the diagonal is overwritten by the elements of the matrix `Vector`.

If `Diagonal` = 0, the main diagonal of the `Matrix` is overwritten. The number $n = \min(\text{number of rows of Matrix}, \text{number of columns of Matrix})$.

Example 1:

$$\text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \end{bmatrix}$$

$$\text{Vector} = \begin{bmatrix} 3.0 & 7.0 & 1.0 \end{bmatrix} \quad \text{Diagonal} = 0$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 7.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 1.0 & 0.0 \end{bmatrix}$$

Example 2:

$$\text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \end{bmatrix}$$

$$\text{Vector} = \begin{bmatrix} 3.0 \end{bmatrix} \quad \text{Diagonal} = 0$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 3.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 3.0 & 0.0 \end{bmatrix}$$

If **Diagonal** is positive, the **Diagonal**-th super-diagonal of **Matrix** is overwritten. For the example 1 the number $n = \min(\text{number of rows of Matrix}, \text{parameter Diagonal})$. For the example 2 the number $n = \min(\text{number of rows of Matrix}, \text{number of columns of Matrix})$.

Example 1:

$$\text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \end{bmatrix}$$

$$\text{Vector} = \begin{bmatrix} -2.0 & 6.0 \end{bmatrix} \quad \text{Diagonal} = 2$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & -2.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 6.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \end{bmatrix}$$

Example 2:

$$\text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \end{bmatrix}$$

$$\text{Vector} = \begin{bmatrix} -2.0 \end{bmatrix} \quad \text{Diagonal} = 2$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & -2.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & -2.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \end{bmatrix}$$

If **Diagonal** is negative, the **Diagonal**-th sub-diagonal of **Matrix** is overwritten. For the example 1 the number $n = \min(\text{number of columns of Matrix}, \text{parameter Diagonal})$. For the example 2 the number $n = \min(\text{number of rows of Matrix}, \text{number of columns of Matrix})$.

Example 1:

$$\text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \end{bmatrix}$$

$$\text{Vector} = \begin{bmatrix} -5.0 & -4.0 \end{bmatrix} \quad \text{Diagonal} = -1$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & 0.0 & 0.0 \\ -5.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & -4.0 & 0.0 & 0.0 \end{bmatrix}$$

Example 2:

$$\text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 \end{bmatrix}$$

$$\text{Vector} = \begin{bmatrix} -5.0 \end{bmatrix} \quad \text{Diagonal} = -1$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & 0.0 & 0.0 \\ -5.0 & 0.0 & 0.0 & 0.0 \\ 0.0 & -5.0 & 0.0 & 0.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **VectorID** (input_control) matrix $\leadsto$ *handle*
Matrix handle containing the diagonal elements to be set.
- ▷ **Diagonal** (input_control) integer $\leadsto$ *integer*
Position of the diagonal.
Default: 0
Suggested values: Diagonal $\in \{-20, -10, -5, -4, -3, -2, -1, 0, 1, 2, 3, 4, 5, 10, 20\}$

Result

If the parameters are valid, the operator `set_diagonal_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MatrixID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

set_full_matrix (: : MatrixID, Values :)

Set all values of a matrix.

The operator `set_full_matrix` sets all elements of the input Matrix defined by the matrix handle `MatrixID`. The values of the parameter `Values` can be a tuple of floating point or integer numbers. Integer numbers are converted to floating point numbers automatically. The parameter `Values` must contain all values in a row-major order, i.e., stored line by line. In addition, the number of elements in `Values` must be 1 or identical to the number of all elements of the matrix.

Note: The same result can be reached with the operator `create_matrix`. The advantage by using the operator `set_full_matrix` is to recycle a matrix that is no longer needed. Thus, the runtime of the operation takes fewer time.

Example 1:

$$\text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 \end{bmatrix} \quad \text{Values} = [3, 1, -2, -5, 7, 2, -9, -4, 1]$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix}$$

Example 2:

$$\text{Matrix} = \begin{bmatrix} 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 \\ 0.0 & 0.0 & 0.0 \end{bmatrix} \quad \text{Values} = [7]$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 7.0 & 7.0 & 7.0 \\ 7.0 & 7.0 & 7.0 \\ 7.0 & 7.0 & 7.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.
- ▷ **Values** (input_control) number(-array) $\leadsto$ real / integer
Values to be set.

Result

If the parameters are valid, the operator `set_full_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MatrixID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

set_sub_matrix (: : MatrixID, MatrixSubID, Row, Column :)

Set a sub-matrix of a matrix.

The operator `set_sub_matrix` *overwrites* a part of the Matrix with the matrix MatrixSub. The input matrices are defined by the matrix handles `MatrixID` and `MatrixSubID`. The parameters `Row` and `Column` determine the position of the upper left corner of the sub-matrix MatrixSub in Matrix.

Example:

`Row = 0, Column = 1`

$$\text{Matrix} = \begin{bmatrix} 3.0 & 0.0 & 9.0 & 1.0 \\ -5.0 & 3.0 & 1.0 & 6.0 \\ -9.0 & 0.0 & 1.0 & -1.0 \end{bmatrix} \quad \text{MatrixSub} = \begin{bmatrix} 1.0 & -2.0 \\ 7.0 & 2.0 \\ -4.0 & 1.0 \end{bmatrix}$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 & 1.0 \\ -5.0 & 7.0 & 2.0 & 6.0 \\ -9.0 & -4.0 & 1.0 & -1.0 \end{bmatrix}$$

Attention

The conditions $0 \leq \text{Row} < \text{size of matrix Matrix in the row direction}$, $\text{Row} + \text{size of matrix MatrixSub in the row direction} \leq \text{size of matrix Matrix in the row direction}$, $0 \leq \text{Column} < \text{size of Matrix in the column direction}$, and $\text{Column} + \text{size of matrix MatrixSub in the columns direction} \leq \text{size of Matrix in the column direction}$ must be satisfied.

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **MatrixSubID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input sub-matrix.
- ▷ **Row** (input_control) integer $\leadsto$ *integer*
Upper row position of the sub-matrix in the matrix.
Default: 0
Suggested values: `Row` $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}$
Restriction: `Row` ≥ 0

- ▷ **Column** (input_control) integer $\leadsto$ integer
 Left column position of the sub-matrix in the matrix.
Default: 0
Suggested values: Column $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}$
Restriction: Column ≥ 0

Result

If the parameters are valid, the operator `set_sub_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MatrixID

set_value_matrix (: : MatrixID, Row, Column, Value :)
--

Set one or more elements of a matrix.

The operator `set_value_matrix` *sets* the values of the elements of the input `Matrix` at the positions (`Row`, `Column`) to the values specified by `Value`. The values can be a tuple of floating point or integer numbers. Integer numbers are converted to floating point numbers automatically. The number of values of `Value` must match the number of elements of `Row` and `Column`. In addition, the conditions $0 \leq \text{Row} < \text{size of Matrix}$ in the row direction and $0 \leq \text{Column} < \text{size of Matrix}$ in the column direction must be satisfied. The `Matrix` is defined by the matrix handle `MatrixID`.

Example:

`Row = [0,2,1]`, `Column = [1,0,3]`, `Value = [1,-9,6]`

$$\text{Matrix} = \begin{bmatrix} 3.0 & 0.0 & -2.0 & 1.0 \\ -5.0 & 7.0 & 2.0 & -2.0 \\ 8.0 & -4.0 & 1.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 & 1.0 \\ -5.0 & 7.0 & 2.0 & 6.0 \\ -9.0 & -4.0 & 1.0 & -1.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **Row** (input_control) integer(-array) $\leadsto$ *integer*
Row numbers of the matrix elements to be modified.
Default: 0
Suggested values: Row $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}$
Restriction: Row ≥ 0
- ▷ **Column** (input_control) integer(-array) $\leadsto$ *integer*
Column numbers of the matrix elements to be modified.
Default: 0
Suggested values: Column $\in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100\}$
Restriction: Column ≥ 0
- ▷ **Value** (input_control) number(-array) $\leadsto$ *real / integer*
Values to be set in the indicated matrix elements.
Default: 0
Suggested values: Value $\in \{0, 1, -1\}$

Result

If the parameters are valid, the operator `set_value_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MatrixID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

19.2 Arithmetic

abs_matrix (: : MatrixID : MatrixAbsID)

Compute the absolute values of the elements of a matrix.

The operator `abs_matrix` computes the absolute values of all elements of the input *Matrix* given by the matrix handle `MatrixID`. A new matrix *MatrixAbs* is generated with the result. The operator returns the matrix handle `MatrixAbsID` of the matrix *MatrixAbs*. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{MatrixAbs}_{ij} = |\text{Matrix}_{ij}|.$$

Example:

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \rightarrow \text{MatrixAbs} = \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.
- ▷ **MatrixAbsID** (output_control) matrix $\leadsto$ handle
Matrix handle with the absolute values of the input matrix.

Result

If the parameters are valid, the operator `abs_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_matrix`

Possible Successors

`get_full_matrix`, `get_value_matrix`

Alternatives

`abs_matrix_mod`

Module

Foundation

abs_matrix_mod (: : MatrixID :)

Compute the absolute values of the elements of a matrix.

The operator `abs_matrix_mod` computes the absolute values of all elements of the input `Matrix` given by the matrix handle `MatrixID`. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{Matrix}_{ij} = |\text{Matrix}_{ij}|.$$

Example:

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.

Result

If the parameters are valid, the operator `abs_matrix_mod` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- **MatrixID**

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

add_matrix (: : MatrixAID, MatrixBID : MatrixSumID)

Add two matrices.

The operator `add_matrix` computes the sum of the input matrices `MatrixA` and `MatrixB` given by the matrix handles `MatrixAID` and `MatrixBID`. Both matrices must have identical dimensions. A new matrix `MatrixSum` is generated with the result. The operator returns the matrix handle `MatrixSumID` of the matrix `MatrixSum`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{MatrixSum} = \text{MatrixA} + \text{MatrixB}.$$

Example:

$$\text{MatrixA} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 2.0 & 8.0 & -3.0 \\ -4.0 & -1.0 & 5.0 \\ 2.0 & -4.0 & 7.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixSum} = \begin{bmatrix} 5.0 & 9.0 & -5.0 \\ -9.0 & 6.0 & 7.0 \\ -7.0 & -8.0 & 8.0 \end{bmatrix}$$

<i>Parameters</i>
▷ MatrixAID (input_control)matrix $\leadsto$ <i>handle</i> Matrix handle of the input matrix A.
▷ MatrixBID (input_control)matrix $\leadsto$ <i>handle</i> Matrix handle of the input matrix B.
▷ MatrixSumID (output_control)matrix $\leadsto$ <i>handle</i> Matrix handle with the sum of the input matrices.

<i>Result</i>

If the parameters are valid, the operator `add_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

<i>Execution Information</i>

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

div_element_matrix (: : MatrixAID, MatrixBID : MatrixDivID)
--

Divide matrices element-by-element.

The operator `div_element_matrix` divides the two matrices `MatrixA` and `MatrixB` element-by-element. The matrices are given by the matrix handles `MatrixAID` and `MatrixBID`. It is required that both input matrices have identical dimensions. The new created output `MatrixDiv` contains the result. The operator returns the matrix handle `MatrixDivID` of the matrix `MatrixDiv`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{MatrixDiv}_{ij} = \text{MatrixA}_{ij} / \text{MatrixB}_{ij}.$$

Example:

$$\text{MatrixA} = \begin{bmatrix} 4.0 & 8.0 & 0.0 \\ -6.0 & 7.0 & 2.0 \\ -9.0 & 4.0 & 1.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 2.0 & 8.0 & -3.0 \\ -4.0 & -1.0 & 4.0 \\ -2.0 & -4.0 & 2.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixDiv} = \begin{bmatrix} 2.0 & 1.0 & 0.0 \\ 1.5 & -7.0 & 0.5 \\ 4.5 & -1.0 & 0.5 \end{bmatrix}$$

<i>Parameters</i>
▷ MatrixAID (input_control) matrix $\leadsto$ handle Matrix handle of the input matrix A. ▷ MatrixBID (input_control) matrix $\leadsto$ handle Matrix handle of the input matrix B. ▷ MatrixDivID (output_control) matrix $\leadsto$ handle Matrix handle with the divided values of input matrices.
<i>Result</i>
If the parameters are valid, the operator <code>div_element_matrix</code> returns the value 2 (<code>H_MSG_TRUE</code>). If necessary, an exception is raised.

invert_matrix (: : MatrixID, MatrixType, Epsilon : MatrixInvID)
--

Invert a matrix.

The operator `invert_matrix` computes the inverse of the Matrix defined by the matrix handle `MatrixID`. A new matrix `MatrixInv` is generated with the result and the matrix handle `MatrixInvID` of this matrix is returned. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`.

For `Epsilon = 0`, the inverse is computed. The type of the Matrix can be selected via `MatrixType`. The following values are supported: `'general'` for general, `'symmetric'` for symmetric, `'positive_definite'` for symmetric positive definite, `'tridiagonal'` for tridiagonal, `'upper_triangular'` for upper triangular, `'permuted_upper_triangular'` for permuted upper triangular, `'lower_triangular'` for lower triangular, and `'permuted_lower_triangular'` for permuted lower triangular matrices.

Example 1:

`MatrixType = 'general', Epsilon = 0`

$$\text{Matrix} = \begin{bmatrix} 1.0 & 3.0 & 3.0 \\ 4.0 & 5.0 & 6.0 \\ 5.0 & 5.0 & 7.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixInv} = \begin{bmatrix} -1.25 & 1.50 & -0.75 \\ -0.50 & 2.00 & -1.50 \\ 1.25 & -2.50 & 1.75 \end{bmatrix}$$

Example 2:

`MatrixType = 'upper_triangular', Epsilon = 0`

$$\text{Matrix} = \begin{bmatrix} 1.0 & 3.0 & 3.0 \\ 0 & 2.0 & 6.0 \\ 0 & 0 & 10.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixInv} = \begin{bmatrix} 1.00 & -1.50 & 0.60 \\ 0 & 0.50 & -0.30 \\ 0 & 0 & 0.10 \end{bmatrix}$$

Example 3:

`MatrixType = 'permuted_upper_triangular', Epsilon = 0`

$$\text{Matrix} = \begin{bmatrix} 1.0 & 3.0 & 3.0 \\ 0 & 0 & 10.0 \\ 0 & 2.0 & 6.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixInv} = \begin{bmatrix} 1.00 & -1.50 & 0.60 \\ 0 & 0.50 & -0.30 \\ 0 & 0 & 0.10 \end{bmatrix}$$

For `Epsilon` > 0, the pseudo inverse is computed using a singular value decomposition (SVD). During the computation, all singular values less than the value `Epsilon` × the largest singular value are set to 0. For these values no internal division is done to prevent a division by zero. If a square matrix is computed with the SVD algorithm the computation takes more time. The type of the matrix must be set to `MatrixType = 'general'`.

Example:

`MatrixType = 'general', Epsilon = 2.2204e-16`

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 & 5.0 \\ -5.0 & 7.0 & 2.0 & -6.0 \\ -9.0 & -4.0 & 1.0 & 4.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixInv} = \begin{bmatrix} -0.0021 & -0.0482 & -0.0813 \\ 0.1435 & 0.1137 & -0.0137 \\ -0.0519 & -0.0015 & 0.0028 \\ 0.1518 & 0.0056 & 0.0526 \end{bmatrix}$$

Note: The relative accuracy of the floating point representation of the used data type (double) is `Epsilon = 2.2204e-16`.

It should be also noted that in the examples there are differences in the meaning of the numbers of the output matrices: The results of the elements are per definition a certain value if the number of this value is shown as an integer number, e.g., 0 or 1. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed.

Attention

For `MatrixType = 'symmetric', 'positive_definite',` or `'upper_triangular'` the upper triangular part of the input `Matrix` must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For `MatrixType = 'lower_triangular'` the lower triangular part of the input `Matrix` must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. For `MatrixType = 'tridiagonal'`, only the main diagonal, the superdiagonal, and the subdiagonal of the input `Matrix` are used. The other parts of the matrix are not referenced. If the referenced part of the input `Matrix` is not of the specified type, an exception is raised.

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **MatrixType** (input_control) string $\leadsto$ *string*
The type of the input matrix.
Default: 'general'
List of values: `MatrixType` ∈ {'general', 'symmetric', 'positive_definite', 'tridiagonal', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}
- ▷ **Epsilon** (input_control) real $\leadsto$ *real*
Type of inversion.
Default: 0.0
Suggested values: `Epsilon` ∈ {0.0, 2.2204e-16}
- ▷ **MatrixInvID** (output_control) matrix $\leadsto$ *handle*
Matrix handle with the inverse matrix.

Result

If the parameters are valid, the operator `invert_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`invert_matrix_mod` (: : `MatrixID`, `MatrixType`, `Epsilon` :)

Invert a matrix.

The operator `invert_matrix_mod` computes the inverse of the `Matrix` defined by the matrix handle `MatrixID`. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`.

For `Epsilon` = 0, the inverse is computed. The type of the `Matrix` can be selected via `MatrixType`. The following values are supported: `'general'` for general, `'symmetric'` for symmetric, `'positive_definite'` for symmetric positive definite, `'tridiagonal'` for tridiagonal, `'upper_triangular'` for upper triangular, `'permuted_upper_triangular'` for permuted upper triangular, `'lower_triangular'` for lower triangular, and `'permuted_lower_triangular'` for permuted lower triangular matrices.

Example 1:

`MatrixType` = `'general'`, `Epsilon` = 0

$$\begin{aligned} \text{Matrix} &= \begin{bmatrix} 1.0 & 3.0 & 3.0 \\ 4.0 & 5.0 & 6.0 \\ 5.0 & 5.0 & 7.0 \end{bmatrix} \\ \rightarrow \quad \text{Matrix} &= \begin{bmatrix} -1.25 & 1.50 & -0.75 \\ -0.50 & 2.00 & -1.50 \\ 1.25 & -2.50 & 1.75 \end{bmatrix} \end{aligned}$$

Example 2:

`MatrixType` = `'upper_triangular'`, `Epsilon` = 0

$$\begin{aligned} \text{Matrix} &= \begin{bmatrix} 1.0 & 3.0 & 3.0 \\ 0 & 2.0 & 6.0 \\ 0 & 0 & 10.0 \end{bmatrix} \\ \rightarrow \quad \text{Matrix} &= \begin{bmatrix} 1.00 & -1.50 & 0.60 \\ 0 & 0.50 & -0.30 \\ 0 & 0 & 0.10 \end{bmatrix} \end{aligned}$$

Example 3:

`MatrixType = 'permuted_upper_triangular', Epsilon = 0`

$$\text{Matrix} = \begin{bmatrix} 1.0 & 3.0 & 3.0 \\ 0 & 0 & 10.0 \\ 0 & 2.0 & 6.0 \end{bmatrix}$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 1.00 & -1.50 & 0.60 \\ 0 & 0.50 & -0.30 \\ 0 & 0 & 0.10 \end{bmatrix}$$

For `Epsilon` > 0, the pseudo inverse is computed using a singular value decomposition (SVD). During the computation, all singular values less than the value `Epsilon` × the largest singular value are set to 0. For these values no internal division is done to prevent a division by zero. If a square matrix is computed with the SVD algorithm the computation takes more time. The type of the matrix must be set to `MatrixType = 'general'`.

Example:

`MatrixType = 'general', Epsilon = 2.2204e-16`

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 & 5.0 \\ -5.0 & 7.0 & 2.0 & -6.0 \\ -9.0 & -4.0 & 1.0 & 4.0 \end{bmatrix}$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} -0.0021 & -0.0482 & -0.0813 \\ 0.1435 & 0.1137 & -0.0137 \\ -0.0519 & -0.0015 & 0.0028 \\ 0.1518 & 0.0056 & 0.0526 \end{bmatrix}$$

Note: The relative accuracy of the floating point representation of the used data type (double) is `Epsilon = 2.2204e-16`.

It should be also noted that in the examples there are differences in the meaning of the numbers of the output matrices: The results of the elements are per definition a certain value if the number of this value is shown as an integer number, e.g., 0 or 1. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed.

Attention

For `MatrixType = 'symmetric', 'positive_definite',` or `'upper_triangular'` the upper triangular part of the input `Matrix` must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For `MatrixType = 'lower_triangular'` the lower triangular part of the input `Matrix` must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. For `MatrixType = 'tridiagonal'`, only the main diagonal, the superdiagonal, and the subdiagonal of the input `Matrix` are used. The other parts of the matrix are not referenced. If the referenced part of the input `Matrix` is not of the specified type, an exception is raised.

`invert_matrix_mod` modifies the content of an already existing matrix.

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.
- ▷ **MatrixType** (input_control) string $\leadsto$ string
The type of the input matrix.
Default: 'general'
List of values: `MatrixType` ∈ {'general', 'symmetric', 'positive_definite', 'tridiagonal', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}
- ▷ **Epsilon** (input_control) real $\leadsto$ real
Type of inversion.
Default: 0.0
Suggested values: `Epsilon` ∈ {0.0, 2.2204e-16}

Result

If the parameters are valid, the operator `invert_matrix_mod` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `MatrixID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

<code>mult_element_matrix</code> (: : <code>MatrixAID</code> , <code>MatrixBID</code> : <code>MatrixMultID</code>)

Multiply matrices element-by-element.

The operator `mult_element_matrix` multiplies the two matrices `MatrixA` and `MatrixB` element-by-element. The matrices are defined by the matrix handles `MatrixAID` and `MatrixBID`. It is required that both input matrices have identical dimensions. A new matrix `MatrixMult` is generated with the result. The operator returns the matrix handle `MatrixMultID` of the matrix `MatrixMult`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{MatrixMult}_{ij} = \text{MatrixA}_{ij} \cdot \text{MatrixB}_{ij}.$$

Example:

$$\text{MatrixA} = \begin{bmatrix} 4.0 & 8.0 & 0.0 \\ -6.0 & 7.0 & 2.0 \\ -9.0 & 4.0 & 1.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 2.0 & 8.0 & -3.0 \\ -4.0 & -1.0 & 4.0 \\ -2.0 & -4.0 & 2.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixMult} = \begin{bmatrix} 8.0 & 64.0 & 0.0 \\ 24.0 & -7.0 & 8.0 \\ 18.0 & -16.0 & 2.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixAID** (input_control)matrix $\leadsto$ handle
Matrix handle of the input matrix A.
- ▷ **MatrixBID** (input_control)matrix $\leadsto$ handle
Matrix handle of the input matrix B.
- ▷ **MatrixMultID** (output_control)matrix $\leadsto$ handle
Matrix handle with the multiplied values of the input matrices.

Result

If the parameters are valid, the operator `mult_element_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

mult_matrix (: : MatrixAID, MatrixBID, MultType : MatrixMultID)

Multiply two matrices.

The operator `mult_matrix` computes the product of the input matrices `MatrixA` and `MatrixB` defined by the matrix handles `MatrixAID` and `MatrixBID`. A new matrix `MatrixMult` is generated with the result. The operator returns the matrix handle `MatrixMultID` of the matrix `MatrixMult`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. If desired, one or both input matrices will be transposed for the multiplication.

The type of multiplication can be selected via `MultType`:

'AB': The matrices `MatrixA` and `MatrixB` will not be transposed. Therefore, the formula for the calculation of the result is:

$$\text{MatrixMult} = \text{MatrixA} \cdot \text{MatrixB}.$$

The number of columns of the matrix `MatrixA` must be identical to the number of rows of the matrix `MatrixB`.

Example:

$$\text{MatrixA} = \begin{bmatrix} 3.0 & -3.0 \\ 2.0 & -5.0 \\ -3.0 & 2.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 3.0 & -3.0 & 1.0 & 1.0 \\ 2.0 & -1.0 & -2.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixMult} = \begin{bmatrix} 3.0 & -6.0 & 9.0 & 6.0 \\ -4.0 & -1.0 & 12.0 & 7.0 \\ -5.0 & 7.0 & -7.0 & -5.0 \end{bmatrix}$$

'**ATB**': The matrix `MatrixA` will be transposed. The matrix `MatrixB` will not be transposed. Therefore, the formula for the calculation of the result is:

$$\text{MatrixMult} = \text{MatrixA}^T \cdot \text{MatrixB}.$$

The number of rows of the matrix `MatrixA` must be identical to the number of rows of the matrix `MatrixB`.

Example:

$$\text{MatrixA} = \begin{bmatrix} 3.0 & 2.0 & -3.0 \\ -3.0 & -5.0 & 2.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 3.0 & -3.0 & 1.0 & 1.0 \\ 2.0 & -1.0 & -2.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixMult} = \begin{bmatrix} 3.0 & -6.0 & 9.0 & 6.0 \\ -4.0 & -1.0 & 12.0 & 7.0 \\ -5.0 & 7.0 & -7.0 & -5.0 \end{bmatrix}$$

'**ABT**': The matrix `MatrixA` will not be transposed. The matrix `MatrixB` will be transposed. Therefore, the formula for the calculation of the result is:

$$\text{MatrixMult} = \text{MatrixA} \cdot \text{MatrixB}^T.$$

The number of columns of the matrix `MatrixA` must be identical to the number of columns of the matrix `MatrixB`.

Example:

$$\text{MatrixA} = \begin{bmatrix} 3.0 & -3.0 \\ 2.0 & -5.0 \\ -3.0 & 2.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 3.0 & 2.0 \\ -3.0 & -1.0 \\ 1.0 & -2.0 \\ 1.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixMult} = \begin{bmatrix} 3.0 & -6.0 & 9.0 & 6.0 \\ -4.0 & -1.0 & 12.0 & 7.0 \\ -5.0 & 7.0 & -7.0 & -5.0 \end{bmatrix}$$

'**ATBT**': The matrix `MatrixA` and the matrix `MatrixB` will be transposed. Therefore, the formula for the calculation of the result is:

$$\text{MatrixMult} = \text{MatrixA}^T \cdot \text{MatrixB}^T.$$

The number of rows of the matrix `MatrixA` must be identical to the number of columns of the matrix `MatrixB`.

Example:

$$\text{MatrixA} = \begin{bmatrix} 3.0 & 2.0 & -3.0 \\ -3.0 & -5.0 & 2.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 3.0 & 2.0 \\ -3.0 & -1.0 \\ 1.0 & -2.0 \\ 1.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixMult} = \begin{bmatrix} 3.0 & -6.0 & 9.0 & 6.0 \\ -4.0 & -1.0 & 12.0 & 7.0 \\ -5.0 & 7.0 & -7.0 & -5.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixAID** (input_control)matrix $\leadsto$ *handle*
Matrix handle of the input matrix A.
- ▷ **MatrixBID** (input_control)matrix $\leadsto$ *handle*
Matrix handle of the input matrix B.
- ▷ **MultType** (input_control)string $\leadsto$ *string*
Type of the input matrices.
Default: 'AB'
List of values: MultType $\in$ {'AB', 'ATB', 'ABT', 'ATBT'}
- ▷ **MatrixMultID** (output_control)matrix $\leadsto$ *handle*
Matrix handle of the multiplied matrices.

Result

If the parameters are valid, the operator `mult_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

mult_matrix_mod (: : MatrixAID, MatrixBID, MultType :)

Multiply two matrices.

The operator `mult_matrix` computes the product of the input matrices `MatrixA` and `MatrixB` defined by the matrix handles `MatrixAID` and `MatrixBID`. The input matrix `MatrixA` is overwritten with the result. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. If desired, one or both input matrices will be transposed for the multiplication.

The type of multiplication can be selected via `MultType`:

'AB': The matrices `MatrixA` and `MatrixB` will not be transposed. Therefore, the formula for the calculation of the result is:

$$\text{MatrixA} = \text{MatrixA} \cdot \text{MatrixB}.$$

The number of columns of the matrix `MatrixA` must be identical to the number of rows of the matrix `MatrixB`.

Example:

$$\text{MatrixA} = \begin{bmatrix} 3.0 & -3.0 \\ 2.0 & -5.0 \\ -3.0 & 2.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 3.0 & -3.0 & 1.0 & 1.0 \\ 2.0 & -1.0 & -2.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixA} = \begin{bmatrix} 3.0 & -6.0 & 9.0 & 6.0 \\ -4.0 & -1.0 & 12.0 & 7.0 \\ -5.0 & 7.0 & -7.0 & -5.0 \end{bmatrix}$$

'*ATB*': The matrix `MatrixA` will be transposed. The matrix `MatrixB` will not be transposed. Therefore, the formula for the calculation of the result is:

$$\text{MatrixA} = \text{MatrixA}^T \cdot \text{MatrixB}.$$

The number of rows of the matrix `MatrixA` must be identical to the number of rows of the matrix `MatrixB`.

Example:

$$\text{MatrixA} = \begin{bmatrix} 3.0 & 2.0 & -3.0 \\ -3.0 & -5.0 & 2.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 3.0 & -3.0 & 1.0 & 1.0 \\ 2.0 & -1.0 & -2.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixA} = \begin{bmatrix} 3.0 & -6.0 & 9.0 & 6.0 \\ -4.0 & -1.0 & 12.0 & 7.0 \\ -5.0 & 7.0 & -7.0 & -5.0 \end{bmatrix}$$

'*ABT*': The matrix `MatrixA` will not be transposed. The matrix `MatrixB` will be transposed. Therefore, the formula for the calculation of the result is:

$$\text{MatrixA} = \text{MatrixA} \cdot \text{MatrixB}^T.$$

The number of columns of the matrix `MatrixA` must be identical to the number of columns of the matrix `MatrixB`.

Example:

$$\text{MatrixA} = \begin{bmatrix} 3.0 & -3.0 \\ 2.0 & -5.0 \\ -3.0 & 2.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 3.0 & 2.0 \\ -3.0 & -1.0 \\ 1.0 & -2.0 \\ 1.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixA} = \begin{bmatrix} 3.0 & -6.0 & 9.0 & 6.0 \\ -4.0 & -1.0 & 12.0 & 7.0 \\ -5.0 & 7.0 & -7.0 & -5.0 \end{bmatrix}$$

'*ATBT*': The matrix `MatrixA` and the matrix `MatrixB` will be transposed. Therefore, the formula for the calculation of the result is:

$$\text{MatrixA} = \text{MatrixA}^T \cdot \text{MatrixB}^T.$$

The number of rows of the matrix `MatrixA` must be identical to the number of columns of the matrix `MatrixB`.

Example:

$$\text{MatrixA} = \begin{bmatrix} 3.0 & 2.0 & -3.0 \\ -3.0 & -5.0 & 2.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 3.0 & 2.0 \\ -3.0 & -1.0 \\ 1.0 & -2.0 \\ 1.0 & -1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixA} = \begin{bmatrix} 3.0 & -6.0 & 9.0 & 6.0 \\ -4.0 & -1.0 & 12.0 & 7.0 \\ -5.0 & 7.0 & -7.0 & -5.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixAID** (input_control)matrix $\leadsto$ handle
Matrix handle of the input matrix A.
- ▷ **MatrixBID** (input_control)matrix $\leadsto$ handle
Matrix handle of the input matrix B.
- ▷ **MultType** (input_control)string $\leadsto$ string
Type of the input matrices.
Default: 'AB'
List of values: MultType $\in$ {'AB', 'ATB', 'ABT', 'ATBT'}

Result

If the parameters are valid, the operator `mult_matrix_mod` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MatrixAID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

pow_element_matrix (: : MatrixID, MatrixExpID : MatrixPowID)

Compute the power functions of the elements of a matrix.

The operator `pow_element_matrix` computes the power of all elements of the input Matrix with the elements of the input matrix MatrixExp. The input matrices Matrix and MatrixExp are defined by the matrix handles `MatrixID` and `MatrixExpID`. Both matrices must have identical dimensions. A new matrix MatrixPow is generated with the result. The operator returns the matrix handle `MatrixPowID` of the matrix MatrixPow. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{MatrixPow}_{ij} = \text{Matrix}_{ij}^{\text{MatrixExp}_{ij}}.$$

Example:

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix} \quad \text{MatrixExp} = \begin{bmatrix} 1.0 & 2.0 & 2.0 \\ 2.0 & 0.0 & 3.0 \\ 0.5 & 3.0 & 1.0 \end{bmatrix}$$

$$\rightarrow \quad \text{MatrixPow} = \begin{bmatrix} 3.0 & 1.0 & 4.0 \\ 25.0 & 1.0 & 8.0 \\ 3.0 & 64.0 & 1.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix of the base.
- ▷ **MatrixExpID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix with exponents.
- ▷ **MatrixPowID** (output_control) matrix $\leadsto$ *handle*
Matrix handle with the raised power of the input matrix.

Result

If the parameters are valid, the operator `pow_element_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

pow_element_matrix_mod (: : MatrixID, MatrixExpID :)

Compute the power functions of the elements of a matrix.

The operator `pow_element_matrix_mod` computes the power of all elements of the input `Matrix` with the elements of the input matrix `MatrixExp`. The input matrices `Matrix` and `MatrixExp` are defined by the matrix handles `MatrixID` and `MatrixExpID`. Both matrices must have identical dimensions. The input `Matrix` is overwritten with the result. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{Matrix}_{ij} = \text{Matrix}_{ij}^{\text{MatrixExp}_{ij}}$$

Example:

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix} \quad \text{MatrixExp} = \begin{bmatrix} 1.0 & 2.0 & 2.0 \\ 2.0 & 0.0 & 3.0 \\ 0.5 & 3.0 & 1.0 \end{bmatrix}$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & 4.0 \\ 25.0 & 1.0 & 8.0 \\ 3.0 & 64.0 & 1.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix of the base.
- ▷ **MatrixExpID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix with exponents.

Result

If the parameters are valid, the operator `pow_element_matrix_mod` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

See also

`sqrt_matrix`, `sqrt_matrix_mod`

Module

Foundation

pow_matrix (: : MatrixID, MatrixType, Power : MatrixPowID)

Compute the power functions of a matrix.

The operator `pow_matrix` computes the power of the input `Matrix` by a constant value. The input `Matrix` is given by the matrix handle `MatrixID`. The power value is given by the parameter `Power`. A new matrix `MatrixPow` is generated with the result. The operator returns the matrix handle `MatrixPowID` of the matrix `MatrixPow`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`.

The type of the `Matrix` can be selected via `MatrixType`. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, 'upper_triangular' for upper triangular, 'permuted_upper_triangular' for permuted upper triangular, 'lower_triangular' for lower triangular, and 'permuted_lower_triangular' for permuted lower triangular matrices. The formula for the calculation of the result is:

$$\text{MatrixPow} = \text{Matrix}^{\text{Power}}.$$

Example:

`Power = [2.0], MatrixType = 'general'`

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixPow} = \begin{bmatrix} 32.0 & 18.0 & 10.0 \\ 68.0 & 62.0 & 26.0 \\ 56.0 & 41.0 & 27.0 \end{bmatrix}$$

Attention

For `MatrixType = 'symmetric', 'positive_definite',` or `'upper_triangular'` the upper triangular part of the input `Matrix` must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For `MatrixType = 'lower_triangular'` the lower triangular part of the input `Matrix` must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. If the referenced part of the input `Matrix` is not of the specified type, an exception is raised.

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **MatrixType** (input_control) string $\leadsto$ *string*
The type of the input matrix.
Default: 'general'
List of values: `MatrixType` $\in$ {'general', 'symmetric', 'positive_definite', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}
- ▷ **Power** (input_control) number $\leadsto$ *real / integer*
The power.
Default: 2.0
Suggested values: `Power` $\in$ {0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0}
- ▷ **MatrixPowID** (output_control) matrix $\leadsto$ *handle*
Matrix handle with the raised powered matrix.

Result

If the parameters are valid, the operator `pow_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

pow_matrix_mod (: : MatrixID, MatrixType, Power :)

Compute the power functions of a matrix.

The operator `pow_matrix_mod` computes the power of the input `Matrix` by a constant value. The input `Matrix` is given by the matrix handle `MatrixID`. The power value is given by the parameter `Power`. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`.

The type of the `Matrix` can be selected via `MatrixType`. The following values are supported: `'general'` for general, `'symmetric'` for symmetric, `'positive_definite'` for symmetric positive definite, `'upper_triangular'` for upper triangular, `'permuted_upper_triangular'` for permuted upper triangular, `'lower_triangular'` for lower triangular, and `'permuted_lower_triangular'` for permuted lower triangular matrices. The formula for the calculation of the result is:

$$\text{Matrix} = \text{Matrix}^{\text{Power}}.$$

Example:

`Power = [2.0], MatrixType = 'general'`

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix}$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 32.0 & 18.0 & 10.0 \\ 68.0 & 62.0 & 26.0 \\ 56.0 & 41.0 & 27.0 \end{bmatrix}$$

Attention

For `MatrixType = 'symmetric', 'positive_definite',` or `'upper_triangular'` the upper triangular part of the input `Matrix` must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For `MatrixType = 'lower_triangular'` the lower triangular part of the input `Matrix` must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. If the referenced part of the input `Matrix` is not of the specified type, an exception is raised.

`pow_matrix_mod` modifies the content of an already existing matrix.

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **MatrixType** (input_control) string $\leadsto$ *string*
The type of the input matrix.
Default: `'general'`
List of values: `MatrixType` $\in$ `{'general', 'symmetric', 'positive_definite', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}`
- ▷ **Power** (input_control) number $\leadsto$ *real / integer*
The power.
Default: `2.0`
Suggested values: `Power` $\in$ `{0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0}`

Result

If the parameters are valid, the operator `pow_matrix_mod` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- `MatrixID`

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

pow_scalar_element_matrix (: : MatrixID, Power : MatrixPowID)

Compute the power functions of the elements of a matrix.

The operator `pow_scalar_element_matrix` computes the power of all elements of the input `Matrix` by a constant value. The input `Matrix` is given by the matrix handle `MatrixID`. The power value `Power` is given by the parameter `Power`. A new matrix `MatrixPow` is generated with the result. The operator returns the matrix handle `MatrixPowID` of the matrix `MatrixPow`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{MatrixPow}_{ij} = \text{Matrix}_{ij}^{\text{Power}}.$$

Example:

`Power = [2.0]`

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixPow} = \begin{bmatrix} 9.0 & 1.0 & 4.0 \\ 25.0 & 49.0 & 4.0 \\ 81.0 & 16.0 & 1.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.
- ▷ **Power** (input_control) number $\leadsto$ real / integer
The power.
Default: 2.0
Suggested values: `Power` $\in$ {0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0}
- ▷ **MatrixPowID** (output_control) matrix $\leadsto$ handle
Matrix handle with the raised power of the input matrix.

Result

If the parameters are valid, the operator `pow_scalar_element_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

scale_matrix (: : MatrixID, Factor : MatrixScaledID)

Scale a matrix.

The operator `scale_matrix` scales the `Matrix` by a constant factor. The matrix is defined by the matrix handle `MatrixID`. A new matrix `MatrixScaled` is generated with the result. The operator returns the matrix handle `MatrixScaledID`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{MatrixScaled}_{ij} = \text{Factor} \cdot \text{Matrix}_{ij}.$$

Example:

`Factor = 1.5`

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -2.0 & 6.0 & 2.0 \\ -5.0 & -4.0 & 1.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixScaled} = \begin{bmatrix} 4.5 & 1.5 & -3.0 \\ -3.0 & 9.0 & 3.0 \\ -7.5 & -6.0 & 1.5 \end{bmatrix}$$

<i>Parameters</i>
▷ MatrixID (input_control) matrix $\leadsto$ <i>handle</i> Matrix handle of the input matrix.
▷ Factor (input_control) number $\leadsto$ <i>real / integer</i> Scale factor. Default: 2.0 Suggested values: <code>Factor</code> $\in$ {0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0}
▷ MatrixScaledID (output_control) matrix $\leadsto$ <i>handle</i> Matrix handle with the scaled elements.

<i>Result</i>

If the parameters are valid, the operator `scale_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

<i>Execution Information</i>

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`scale_matrix_mod` (: : MatrixID, Factor :)

Scale a matrix.

The operator `scale_matrix` scales the `Matrix` by a constant factor. The matrix is defined by the matrix handle `MatrixID`. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{Matrix}_{ij} = \text{Factor} \cdot \text{Matrix}_{ij}.$$

Example:

`Factor` = 1.5

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -2.0 & 6.0 & 2.0 \\ -5.0 & -4.0 & 1.0 \end{bmatrix}$$

$$\rightarrow \text{Matrix} = \begin{bmatrix} 4.5 & 1.5 & -3.0 \\ -3.0 & 9.0 & 3.0 \\ -7.5 & -6.0 & 1.5 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **Factor** (input_control) number $\leadsto$ *real / integer*
Scale factor.
Default: 2.0
Suggested values: `Factor` $\in$ {0.1, 0.2, 0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 10.0}

Result

If the parameters are valid, the operator `scale_matrix_mod` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MatrixID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

solve_matrix (: : MatrixLHSID, MatrixLHSType, Epsilon,
MatrixRHSID : MatrixResultID)

Compute the solution of a system of equations.

The operator `solve_matrix` computes the solution of a system of linear equations or of a linear least squares problem. The input matrices `MatrixLHS` and `MatrixRHS` are defined by the matrix handles `MatrixLHSID` and `MatrixRHSID`. The number of rows of matrices `MatrixLHS` and `MatrixRHS` must be identical. The operator returns the matrix handle `MatrixResultID` of the matrix `MatrixResult`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`.

For linear equation systems, the equations

$$\text{MatrixLHS} \cdot \text{MatrixResult} = \text{MatrixRHS}$$

are solved. Therefore, the matrix `MatrixLHS` must be a square matrix and the parameter `Epsilon` must be 0. The type of the matrix `MatrixLHS` can be selected via the parameter `MatrixLHSType`. The following values are supported: `'general'` for general, `'symmetric'` for symmetric, `'positive_definite'` for symmetric positive definite, `'tridiagonal'` for tridiagonal, `'upper_triangular'` for upper triangular, `'permuted_upper_triangular'` for permuted upper triangular, `'lower_triangular'` for lower triangular, and `'permuted_lower_triangular'` for permuted lower triangular matrices.

Example:

`MatrixLHSType = 'positive_definite', Epsilon = 0`

$$\text{MatrixLHS} = \begin{bmatrix} 6.0 & 5.0 & 3.0 \\ 5.0 & 7.0 & 3.0 \\ 3.0 & 3.0 & 4.0 \end{bmatrix} \quad \text{MatrixRHS} = \begin{bmatrix} -1.0 & 6.0 \\ 3.0 & -3.0 \\ 5.0 & 4.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixResult} = \begin{bmatrix} -2.0 & 3.0 \\ 1.0 & -3.0 \\ 2.0 & 1.0 \end{bmatrix}$$

For linear least squares problems or if `Epsilon` is not 0, the matrix `MatrixLHS` need not be a square matrix. The linear least squares problem is solved using the singular value decomposition (SVD) of the matrix `MatrixLHS` by minimizing

$$\|\text{MatrixRHS} - \text{MatrixLHS} \cdot \text{MatrixResult}\|.$$

All singular values less than the value `Epsilon × the largest singular value` are set to 0. For these values no internal division is done to prevent a division by zero. Also, the matrix `MatrixLHS` may be rank-deficient. The type of matrix must be selected via `MatrixLHSType = 'general'`.

Example:

`MatrixLHSType = 'general', Epsilon = 2.2204e-16`

$$\text{MatrixLHS} = \begin{bmatrix} 6.0 & 5.0 & 3.0 \\ 3.0 & 7.0 & -3.0 \\ 5.0 & 12.0 & 4.0 \\ 5.0 & 4.0 & 12.0 \\ 4.0 & 6.0 & 8.0 \end{bmatrix} \quad \text{MatrixRHS} = \begin{bmatrix} 29.0 \\ 10.0 \\ 35.0 \\ 43.0 \\ 25.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixResult} = \begin{bmatrix} 3.4914 \\ 0.7114 \\ 1.6213 \end{bmatrix}$$

Note: The relative accuracy of the floating point representation of the used data type (double) is `Epsilon = 2.2204e-16`.

Attention

For `MatrixLHSType = 'symmetric', 'positive_definite',` or `'upper_triangular'` the upper triangular part of the input `MatrixLHS` must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For `MatrixLHSType = 'lower_triangular'` the lower triangular part of the input `MatrixLHS` must contain the relevant information of the matrix. The strictly upper triangular part of the matrix is not referenced. For `MatrixLHSType = 'tridiagonal'`, only the main diagonal, the superdiagonal, and the subdiagonal of the input `MatrixLHS` are used. The other parts of the matrix are not referenced. If the referenced part of the input `MatrixLHS` is not of the specified type, an exception is raised.

Parameters

- ▷ **MatrixLHSID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix of the left hand side.
- ▷ **MatrixLHSType** (input_control) string $\leadsto$ *string*
The type of the input matrix of the left hand side.
Default: 'general'
List of values: `MatrixLHSType` $\in$ {'general', 'symmetric', 'positive_definite', 'tridiagonal', 'upper_triangular', 'permuted_upper_triangular', 'lower_triangular', 'permuted_lower_triangular'}
- ▷ **Epsilon** (input_control) real $\leadsto$ *real*
Type of solving and limitation to set singular values to be 0.
Default: 0.0
Suggested values: `Epsilon` $\in$ {0.0, 2.2204e-16}
- ▷ **MatrixRHSID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix of right hand side.
- ▷ **MatrixResultID** (output_control) matrix $\leadsto$ *handle*
New matrix handle with the solution.

Result

If the parameters are valid, the operator `solve_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

sqrt_matrix (: : MatrixID : MatrixSqrtID)

Compute the square root values of the elements of a matrix.

The operator `sqrt_matrix` computes the square root values of all elements of the input `Matrix` given by the matrix handle `MatrixID`. A new matrix `MatrixSqrt` is generated with the result. The operator returns the matrix handle `MatrixSqrtID` of the matrix `MatrixSqrt`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{MatrixSqrt}_{ij} = \sqrt{\text{Matrix}_{ij}}.$$

Example:

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix} \rightarrow \text{MatrixSqrt} = \begin{bmatrix} 1.7321 & 1.0000 & 1.4142 \\ 2.2361 & 2.6458 & 1.4142 \\ 3.0000 & 2.0000 & 1.0000 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **MatrixSqrtID** (output_control) matrix $\leadsto$ *handle*
Matrix handle with the square root values of the input matrix.

Result

If the parameters are valid, the operator `sqrt_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

sqrt_matrix_mod (: : MatrixID :)

Compute the square root values of the elements of a matrix.

The operator `sqrt_matrix_mod` computes the square root values of all elements of the input `Matrix` given by the matrix handle `MatrixID`. The input matrix is overwritten with the result. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{Matrix}_{ij} = \sqrt{\text{Matrix}_{ij}}.$$

Example:

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & 2.0 \\ 5.0 & 7.0 & 2.0 \\ 9.0 & 4.0 & 1.0 \end{bmatrix} \rightarrow \text{Matrix} = \begin{bmatrix} 1.7321 & 1.0000 & 1.4142 \\ 2.2361 & 2.6458 & 1.4142 \\ 3.0000 & 2.0000 & 1.0000 \end{bmatrix}$$

Parameters

▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.

Result

If the parameters are valid, the operator `sqrt_matrix_mod` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

sub_matrix (: : <code>MatrixAID</code> , <code>MatrixBID</code> : <code>MatrixSubID</code>)
--

Subtract two matrices.

The operator `sub_matrix` computes the difference of the input matrices `MatrixA` and `MatrixB` given by the matrix handles `MatrixAID` and `MatrixBID`. Both matrices must have identical dimensions. A new matrix `MatrixSub` is generated with the result. The operator returns the matrix handle `MatrixSubID` of the matrix `MatrixSub`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The formula for the calculation of the result is:

$$\text{MatrixSub} = \text{MatrixA} - \text{MatrixB}.$$

Example:

$$\text{MatrixA} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \quad \text{MatrixB} = \begin{bmatrix} 2.0 & 8.0 & -3.0 \\ -4.0 & -1.0 & 5.0 \\ 2.0 & -4.0 & 7.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixSub} = \begin{bmatrix} 1.0 & -7.0 & 1.0 \\ -1.0 & 8.0 & -3.0 \\ -11.0 & 0.0 & -6.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixAID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix A.
- ▷ **MatrixBID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix B.
- ▷ **MatrixSubID** (output_control) matrix $\leadsto$ handle
Matrix handle with the difference of the input matrices.

Result

If the parameters are valid, the operator `sub_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

transpose_matrix (: : MatrixID : MatrixTransposedID)

Transpose a matrix.

The operator `transpose_matrix` returns the transpose of the input Matrix. The input matrix is defined by the matrix handle `MatrixID`. A new matrix `MatrixTransposed` is generated with the result and the matrix handle `MatrixTransposedID` of this matrix is returned. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`.

Example:

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \quad \rightarrow \quad \text{MatrixTransposed} = \begin{bmatrix} 3.0 & -5.0 & -9.0 \\ 1.0 & 7.0 & -4.0 \\ -2.0 & 2.0 & 1.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.
- ▷ **MatrixTransposedID** (output_control) matrix $\leadsto$ handle
Matrix handle with the transpose of the input matrix.

Result

If the parameters are valid, the operator `transpose_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Foundation

19.3 Creation

clear_matrix (: : MatrixID :)

Free the memory of a matrix.

The operator `clear_matrix` frees the memory of the matrix `Matrix` given by the matrix handle `MatrixID`. After calling `clear_matrix`, the `Matrix` can no longer be used. The matrix handle `MatrixID` becomes invalid.

Parameters

▷ **MatrixID** (input_control) matrix(-array) $\leadsto$ *handle*
Matrix handle.

Result

If the parameters are valid, the operator `clear_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MatrixID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

[create_matrix](#)

Module

Foundation

copy_matrix (: : MatrixID : MatrixCopyID)

Copy a matrix.

The operator `copy_matrix` creates the new matrix `MatrixCopy` and copies all elements of the input `Matrix` to this new matrix. The input `Matrix` is defined by the matrix handle `MatrixID`. The operator returns the matrix handle `MatrixCopyID` of the matrix `MatrixCopy`. Access to the elements of the matrix is possible e.g., with

the operator `get_full_matrix`. With this operator a matrix can be saved before the matrix is modified by the operators `set_value_matrix`, `set_full_matrix`, `set_sub_matrix`, or `set_diagonal_matrix`.

Example:

$$\text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix} \rightarrow \text{MatrixCopy} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.
- ▷ **MatrixCopyID** (output_control) matrix $\leadsto$ handle
Matrix handle of the copied matrix.

Result

If the parameters are valid, the operator `copy_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_matrix`

Possible Successors

`get_full_matrix`, `get_value_matrix`

Alternatives

`repeat_matrix`

Module

Foundation

create_matrix (: : Rows, Columns, Value : MatrixID)

Create a matrix.

The operator `create_matrix` creates a new Matrix with `Rows` rows and `Columns` columns and returns the matrix handle `MatrixID`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`. The parameter `Value` is a string or a tuple of floating point or integer numbers. Integer numbers are converted to floating point numbers automatically.

If `Value` = 'identity', `Rows` and `Columns` must have the identical values and an identity matrix is created.

Example:

`Rows` = 3, `Columns` = 3, `Value` = 'identity'

$$\rightarrow \text{Matrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

If the parameter `Value` contains a single value, all elements of the matrix are filled with this value.

Example:

`Rows` = 3, `Columns` = 3, `Value` = 7

$$\rightarrow \text{Matrix} = \begin{bmatrix} 7.0 & 7.0 & 7.0 \\ 7.0 & 7.0 & 7.0 \\ 7.0 & 7.0 & 7.0 \end{bmatrix}$$

If **Value** contains as many values as the main diagonal, all elements of the main diagonal are set to the values of the parameter **Value** (i.e., the number of elements in **Value** is identical).

Example:

Rows = 3, **Columns** = 4, **Value** = [3,7,1]

$$\rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 0 & 0 & 0 \\ 0 & 7.0 & 0 & 0 \\ 0 & 0 & 1.0 & 0 \end{bmatrix}$$

It is also possible to set all elements of the matrix with different values. In this case the parameter **Value** must contain all values in a row-major order, i.e., stored line by line. In addition, the number of elements of **Value** must be identical to the number of all elements of the matrix, i.e., **Rows** × **Columns**.

Example:

Rows = 3, **Columns** = 3, **Value** = [3,1,-2,-5,7,2,-9,-4,1]

$$\rightarrow \text{Matrix} = \begin{bmatrix} 3.0 & 1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \\ -9.0 & -4.0 & 1.0 \end{bmatrix}$$

It should be noted that in the examples there are differences in the meaning of the values of the output matrices: If a value is shown as an integer number, e.g., 0 or 1, the value of this element is per definition this certain value. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed by the operator.

Parameters

- ▷ **Rows** (input_control) integer $\leadsto$ integer
Number of rows of the matrix.
Default: 3
Suggested values: Rows ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100}
Restriction: Rows ≥ 1
- ▷ **Columns** (input_control) integer $\leadsto$ integer
Number of columns of the matrix.
Default: 3
Suggested values: Columns ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 50, 100}
Restriction: Columns ≥ 1
- ▷ **Value** (input_control) number(-array) $\leadsto$ real / integer / string
Values for initializing the elements of the matrix.
Default: 0
Suggested values: Value ∈ {0, 1, 'identity'}
- ▷ **MatrixID** (output_control) matrix $\leadsto$ handle
Matrix handle.

Result

If the parameters are valid, the operator `create_matrix` returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`set_full_matrix`, `clear_matrix`

Module

Foundation

repeat_matrix (: : MatrixID, Rows, Columns : MatrixRepeatedID)

Repeat a matrix.

The operator `repeat_matrix` creates the new matrix `MatrixRepeated` and copies all elements of the input `Matrix` n times to this new matrix, where $n = \text{Rows} \cdot \text{Columns}$. The new matrix has dimensions `Rows` $\times$ rows of the input `Matrix` and `Columns` $\times$ columns of the input `Matrix`. The input `Matrix` is defined by the matrix handle `MatrixID`. The operator returns the matrix handle `MatrixRepeatedID` of the matrix `MatrixRepeated`. Access to the elements of the matrix is possible e.g., with the operator `get_full_matrix`.

Example:

`Rows = 2, Columns = 3`

$$\text{Matrix} = \begin{bmatrix} 3.0 & -1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixRepeated} = \begin{bmatrix} 3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0 \\ 3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 & 3.0 & -1.0 & -2.0 \\ -5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0 & -5.0 & 7.0 & 2.0 \end{bmatrix}$$

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ handle
Matrix handle of the input matrix.
- ▷ **Rows** (input_control) integer $\leadsto$ integer
Number of copies of input matrix in row direction.
Default: 2
Suggested values: `Rows` $\in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20\}$
Restriction: `Rows` ≥ 1
- ▷ **Columns** (input_control) integer $\leadsto$ integer
Number of copies of input matrix in column direction.
Default: 2
Suggested values: `Columns` $\in \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20\}$
Restriction: `Columns` ≥ 1
- ▷ **MatrixRepeatedID** (output_control) matrix $\leadsto$ handle
Matrix handle of the repeated copied matrix.

Result

If the parameters are valid, the operator `repeat_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

19.4 Decomposition

decompose_matrix (: : MatrixID, MatrixType : Matrix1ID,
Matrix2ID)

Decompose a matrix.

The operator `decompose_matrix` decomposes the square input `Matrix` given by the matrix handle `MatrixID`. The results are stored in two generated matrices `Matrix1` and `Matrix2`. The operator returns the matrix handles `Matrix1ID` and `Matrix2ID`. Access to the elements of the matrices is possible e.g., with the operator `get_full_matrix`.

The type of the input `Matrix` can be selected via the parameter `MatrixType`. The following values are supported: 'general' for general, 'symmetric' for symmetric, 'positive_definite' for symmetric positive definite, and 'tridiagonal' for tridiagonal matrices.

The decomposition `MatrixType` = 'general' or 'tridiagonal' is a LU factorization (Lower/Upper) with the form

$$\text{Matrix} = \text{Matrix1} \cdot \text{Matrix2}.$$

The output `Matrix1` is a lower triangular matrix with unit diagonal elements and interchanged rows. The output `Matrix2` is an upper triangular matrix.

Example for a factorization of a general matrix:

$$\text{Matrix} = \begin{bmatrix} 5.0 & -3.0 & 1.0 \\ 0.0 & 2.0 & -1.0 \\ -5.0 & -1.0 & 5.0 \end{bmatrix}$$

$$\rightarrow \quad \text{Matrix1} = \begin{bmatrix} 1 & 0 & 0 \\ 0.0 & -0.5 & 1 \\ -1.0 & 1 & 0 \end{bmatrix} \quad \text{Matrix2} = \begin{bmatrix} 5.0 & -3.0 & 1.0 \\ 0 & -4.0 & 6.0 \\ 0 & 0 & 2.0 \end{bmatrix}$$

Example for a factorization of a tridiagonal matrix:

$$\text{Matrix} = \begin{bmatrix} -8.0 & -8.0 & 0.0 & 0.0 \\ -8.0 & 6.0 & -4.0 & 0.0 \\ 0.0 & 7.0 & -2.0 & 7.0 \\ 0.0 & 0.0 & 5.0 & -3.0 \end{bmatrix}$$

$$\rightarrow \quad \text{Matrix1} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 1.0 & 1 & 0 & 0 \\ 0.0 & 0.5 & 0.0 & 1 \\ 0.0 & 0.0 & 1 & 0 \end{bmatrix} \quad \text{Matrix2} = \begin{bmatrix} -8.0 & -8.0 & 0.0 & 0.0 \\ 0 & 14.0 & -4.0 & 0.0 \\ 0 & 0 & 5.0 & -3.0 \\ 0 & 0 & 0 & 7.0 \end{bmatrix}$$

For `MatrixType` = 'symmetric' the factorization is a UDU^T decomposition (Upper/Diagonal/Upper) with the form

$$\text{Matrix} = \text{Matrix1} \cdot \text{Matrix2} \cdot \text{Matrix1}^T$$

where the output `Matrix1` is an upper triangular matrix with interchanged columns. The output matrix `Matrix2` is a symmetric block diagonal matrix with 1×1 and 2×2 diagonal blocks.

Example for a factorization of a symmetric matrix:

$$\text{Matrix} = \begin{bmatrix} 3.0 & -2.0 & 7.0 & -1.0 \\ -2.0 & -2.0 & 4.0 & 0.0 \\ 7.0 & 4.0 & 8.0 & 1.0 \\ -1.0 & 0.0 & 1.0 & 0.0 \end{bmatrix}$$

$$\rightarrow \text{Matrix1} = \begin{bmatrix} 0 & 0 & 1 & 0.0 \\ 0 & 1 & 0.0 & 2.0 \\ 1 & -1.0 & -1.0 & -10.0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{Matrix2} = \begin{bmatrix} 27.0 & 0 & 0 & 0 \\ 0 & -2.0 & 0 & 0 \\ 0 & 0 & 3.0 & -1.0 \\ 0 & 0 & -1.0 & 0.0 \end{bmatrix}$$

For `MatrixType = 'positive_definite'` a Cholesky factorization is computed with the form

$$\text{Matrix} = \text{Matrix1} \cdot \text{Matrix2}.$$

where the output `Matrix1` is a lower triangular matrix and the output matrix `Matrix2` is an upper triangular matrix. Furthermore, the `Matrix2` is the transpose of the matrix `Matrix1`.

Example for a factorization of a positive definite matrix:

$$\text{Matrix} = \begin{bmatrix} 9.0 & 12.0 & -6.0 \\ 12.0 & 17.0 & -7.0 \\ -6.0 & -7.0 & 14.0 \end{bmatrix}$$

$$\rightarrow \text{Matrix1} = \begin{bmatrix} 3.0 & 0 & 0 \\ 4.0 & 1.0 & 0 \\ -2.0 & 1.0 & 3.0 \end{bmatrix} \quad \text{Matrix2} = \begin{bmatrix} 3.0 & 4.0 & -2.0 \\ 0 & 1.0 & 1.0 \\ 0 & 0 & 3.0 \end{bmatrix}$$

It should be noted that in the examples there are differences in the meaning of the values of the output matrices: If a value is shown as an integer number, e.g., 0 or 1, the value of this element is per definition this certain value. If the number is shown as a floating point number, e.g., 0.0 or 1.0, the value is computed by the operator.

Attention

For `MatrixType = 'symmetric'` or `'positive_definite'`, the upper triangular part of the input `Matrix` must contain the relevant information of the matrix. The strictly lower triangular part of the matrix is not referenced. For `MatrixType = 'tridiagonal'`, only the main diagonal, the superdiagonal, and the subdiagonal of the input `Matrix` are used. The other parts of the matrix are not referenced. If the referenced part of the input `Matrix` is not of the specified type, an exception is raised.

Parameters

- ▷ **MatrixID** (input_control) matrix $\leadsto$ *handle*
Matrix handle of the input matrix.
- ▷ **MatrixType** (input_control) string $\leadsto$ *string*
Type of the input matrix.
Default: 'general'
List of values: `MatrixType` $\in$ {'general', 'symmetric', 'positive_definite', 'tridiagonal'}
- ▷ **Matrix1ID** (output_control) matrix $\leadsto$ *handle*
Matrix handle with the output matrix 1.
- ▷ **Matrix2ID** (output_control) matrix $\leadsto$ *handle*
Matrix handle with the output matrix 2.

Result

If the parameters are valid, the operator `decompose_matrix` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

```
orthogonal_decompose_matrix ( : : MatrixID, DecompositionType,
    OutputMatricesType, ComputeOrthogonal : MatrixOrthogonalID,
    MatrixTriangularID )
```

Perform an orthogonal decomposition of a matrix.

The operator `orthogonal_decompose_matrix` decomposes the `Matrix` defined by the matrix handle `MatrixID`. The results are stored in the two generated matrices `MatrixOrthogonal` and `MatrixTriangular`. The operator returns the matrix handles `MatrixOrthogonalID` and `MatrixTriangularID` of these two matrices. Access to the elements of the matrices is possible e.g., with the operator `get_full_matrix`.

For `OutputMatricesType` = 'full' all results of the decomposition are stored in the matrices `MatrixOrthogonal` and `MatrixTriangular`. For `OutputMatricesType` = 'reduced' only a part of result elements of the matrices `MatrixOrthogonal` and `MatrixTriangular` are stored. Therefore the sizes of these matrices are smaller than for `OutputMatricesType` = 'full'.

For the parameter `ComputeOrthogonal` = 'true' both output matrices are computed. For the `ComputeOrthogonal` = 'false' only the matrix `MatrixTriangular` is computed. Thus, the runtime of the operation takes fewer time.

The type of the `Matrix` can be selected via the parameter `DecompositionType`. For `DecompositionType` = 'qr' a QR decomposition (Quadratic/Right) or for `DecompositionType` = 'ql' a QL decomposition (Quadratic/Left) is computed. The decomposition is written as

$$\text{Matrix} = \text{MatrixOrthogonal} \cdot \text{MatrixTriangular}.$$

Example:

`DecompositionType` = 'qr', `OutputMatricesType` = 'full'

$$\text{Matrix} = \begin{bmatrix} 6.0 & -3.0 & 4.0 \\ 5.0 & 5.0 & -2.0 \\ -3.0 & 12.0 & 5.0 \\ 3.0 & 4.0 & 7.0 \\ 7.0 & 5.0 & 3.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixOrthogonal} = \begin{bmatrix} -0.5303 & 0.2613 & -0.4277 & -0.5566 & -0.3972 \\ -0.4419 & -0.2920 & -0.6383 & 0.1727 & -0.5312 \\ 0.2652 & -0.8443 & -0.2059 & -0.3961 & -0.1326 \\ -0.2652 & -0.2432 & -0.6008 & 0.7000 & -0.1400 \\ -0.6187 & -0.2729 & 0.0799 & -0.1160 & 0.7231 \end{bmatrix}$$

$$\text{MatrixTriangular} = \begin{bmatrix} -11.3137 & -1.5910 & -3.6239 \\ 0 & -14.7129 & -5.1135 \\ 0 & 0 & -7.9824 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

Example:

`DecompositionType = 'qr', OutputMatricesType = 'reduced'`

$$\text{Matrix} = \begin{bmatrix} 6.0 & -3.0 & 4.0 \\ 5.0 & 5.0 & -2.0 \\ -3.0 & 12.0 & 5.0 \\ 3.0 & 4.0 & 7.0 \\ 7.0 & 5.0 & 3.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixOrthogonal} = \begin{bmatrix} -0.5303 & 0.2613 & -0.4277 \\ -0.4419 & -0.2920 & -0.6383 \\ 0.2652 & -0.8443 & -0.2059 \\ -0.2652 & -0.2432 & -0.6008 \\ -0.6187 & -0.2729 & 0.0799 \end{bmatrix}$$

$$\text{MatrixTriangular} = \begin{bmatrix} -11.3137 & -1.5910 & -3.6239 \\ 0 & -14.7129 & -5.1135 \\ 0 & 0 & -7.9824 \end{bmatrix}$$

Example:

`DecompositionType = 'ql', OutputMatricesType = 'full'`

$$\text{Matrix} = \begin{bmatrix} 6.0 & -3.0 & 4.0 \\ 5.0 & 5.0 & -2.0 \\ -3.0 & 12.0 & 5.0 \\ 3.0 & 4.0 & 7.0 \\ 7.0 & 5.0 & 3.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixOrthogonal} = \begin{bmatrix} 0.6806 & 0.0657 & 0.3659 & -0.4932 & -0.3941 \\ 0.1161 & 0.5464 & 0.6091 & 0.5274 & 0.1971 \\ 0.4093 & -0.0832 & -0.4046 & 0.6474 & -0.4927 \\ -0.5362 & 0.4713 & 0.0072 & -0.1208 & -0.6897 \\ -0.2611 & -0.6842 & 0.5757 & 0.2119 & -0.2956 \end{bmatrix}$$

$$\text{MatrixTriangular} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 10.5059 & 0 & 0 \\ -1.1429 & 12.4620 & 0 \\ -4.0399 & -7.9812 & -10.1489 \end{bmatrix}$$

Example:

`DecompositionType = 'ql', OutputMatricesType = 'reduced'`

$$\text{Matrix} = \begin{bmatrix} 6.0 & -3.0 & 4.0 \\ 5.0 & 5.0 & -2.0 \\ -3.0 & 12.0 & 5.0 \\ 3.0 & 4.0 & 7.0 \\ 7.0 & 5.0 & 3.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixOrthogonal} = \begin{bmatrix} 0.3659 & -0.4932 & -0.3941 \\ 0.6091 & 0.5274 & 0.1971 \\ -0.4046 & 0.6474 & -0.4927 \\ 0.0072 & -0.1208 & -0.6897 \\ 0.5757 & 0.2119 & -0.2956 \end{bmatrix}$$

$$\text{MatrixTriangular} = \begin{bmatrix} 10.5059 & 0 & 0 \\ -1.1429 & 12.4620 & 0 \\ -4.0399 & -7.9812 & -10.1489 \end{bmatrix}$$

For `DecompositionType = 'rq'` a RQ decomposition (Right/Quadratic) or for `DecompositionType = 'lq'` a LQ decomposition (Left/Quadratic) is computed. The decomposition is written as

$$\text{Matrix} = \text{MatrixTriangular} \cdot \text{MatrixOrthogonal}.$$

Example:

`DecompositionType = 'rq', OutputMatricesType = 'full'`

$$\text{Matrix} = \begin{bmatrix} 6.0 & 5.0 & -3.0 & 3.0 & 7.0 \\ -3.0 & 5.0 & 12.0 & 4.0 & 5.0 \\ 4.0 & -2.0 & 5.0 & 7.0 & 3.0 \end{bmatrix}$$

$$\rightarrow \text{MatrixOrthogonal} = \begin{bmatrix} 0.6806 & 0.1161 & 0.4093 & -0.5362 & -0.2611 \\ 0.0657 & 0.5464 & -0.0832 & 0.4713 & -0.6842 \\ 0.3659 & 0.6091 & -0.4046 & 0.0072 & 0.5757 \\ -0.4932 & 0.5274 & 0.6474 & -0.1208 & 0.2119 \\ -0.3941 & 0.1971 & -0.4927 & -0.6897 & -0.2956 \end{bmatrix}$$

$$\text{MatrixTriangular} = \begin{bmatrix} 0 & 0 & 10.5059 & -1.1429 & -4.0399 \\ 0 & 0 & 0 & 12.4620 & -7.9812 \\ 0 & 0 & 0 & 0 & -10.1489 \end{bmatrix}$$

Example:
